

BMJ Open is committed to open peer review. As part of this commitment we make the peer review history of every article we publish publicly available.

When an article is published we post the peer reviewers' comments and the authors' responses online. We also post the versions of the paper that were used during peer review. These are the versions that the peer review comments apply to.

The versions of the paper that follow are the versions that were submitted during the peer review process. They are not the versions of record or the final published versions. They should not be cited or distributed as the published version of this manuscript.

BMJ Open is an open access journal and the full, final, typeset and author-corrected version of record of the manuscript is available on our site with no access controls, subscription charges or pay-per-view fees (<u>http://bmjopen.bmj.com</u>).

If you have any questions on BMJ Open's open peer review process please email <u>info.bmjopen@bmj.com</u>

Study Protocol for the G-SPIRIT trial: A Randomized, Placebo-Controlled, Double-blinded Phase 3 Trial of Granulocyte Colony Stimulating Factor-Mediated Neuroprotection for Acute Spinal Cord Injury

Journal:	BMJ Open

Abstract

Introduction: Granulocyte Colony Stimulating Factor (G-CSF) is generally used for neutropenia. Previous experimental studies revealed that G-CSF promoted neurological recovery after spinal cord injury (SCI). Next we moved to early phase of clinical trials. In a phase 1/2a trial, no adverse events were observed. Next, we conducted a non-randomized, non-blinded, comparative trial, which suggested the efficacy of G-CSF for promoting neurological recovery. Based on those results, we are now performing a phase 3 trial. Methods and Analysis: The objective of this study is to prove the efficacy of G-CSF for acute SCI. The study design is a prospective, multicenter, randomized, double-blinded, placebo-controlled comparative study. The current trial includes cervical SCI (severity of American Spinal Injury Association (ASIA) Impairment Scale B/C) within 48 hours after injury. Patients are randomly assigned to G-CSF and placebo groups. The G-CSF group is administered 400 μ g/m²/d×5d of G-CSF in normal saline via intravenous infusion for 5 consecutive days. The placebo group is similarly administered a placebo. Our primary endpoint is changes in ASIA motor scores from baseline to 3 months. Each group includes 44 patients (88 total patients). This trial is funded by the Center for Clinical Trials, Japan Medical Association.

Ethics and Dissemination: The study was approved by the Institutional Review Board of each institution and will be conducted according to the principles of the World Medical Association Declaration of Helsinki and in accordance with the Japanese Medical Research Involving Human Subjects Act and other guidelines, regulations and Acts. Results of the clinical study will be submitted to the head of the respective clinical study site as a report after conclusion of the clinical study by the sponsor-investigator. Even if the results are not favorable despite conducting the clinical study properly, the data will be published as a paper.

Strengths and Limitations of This Study

Strengths

- ✓ Novel drug therapy for acute spinal cord injury is much-needed.
- ✓ Randomized, placebo-controlled, double-blinded design can eliminate bias.

Limitations

- \checkmark Acute spinal cord injury patients are difficult to recruit to the trial.
- Patient's neurological status in acute phase is unstable, possibly resulting in dispersion of the patient's background.
- ✓ Concealment must be performed very strictly because G-CSF apparently increases

white blood cell count.

Introduction

Spinal cord injury (SCI) is a devastating injury by which the patient can suffer from long-lasting severe sequelae including palsy of extremities, sensory disturbance, bowel/bladder/sexual dysfunction, and neuropathic pain. Conceptually, SCI is divided into two chronological phases: a primary and a secondary phase. Primary injury is mechanical damage to spinal cord tissue itself caused by fracture and/or dislocation or compression. Secondary injury is triggered by the primary injury and is a biological reaction of the spinal cord, which includes ischemia, hemorrhage, excitotoxicity, hyperpermeability, and inflammation¹. Because secondary injury can be the main target of treatment, extensive laboratory and clinical investigation of neuroprotection is needed to manage secondary injury².

To date, the only approved neuroprotective therapy for SCI is massive methylprednisolone sodium succinate (MPSS) therapy based on the NASCIS 2 study³. However, recent reports revealed that MPSS shows only a modest effect for SCI. In addition, several reports have described adverse events induced by MPSS for SCI including infections (pneumonia, urinary tract infection) and gastrointestinal disorders (gastric ulcer, etc.)⁴. Therefore, the use of MPSS for SCI has become controversial⁵. Accordingly, a new therapeutic drug for SCI is desirable.

Granulocyte colony-stimulating factor (G-CSF, generic name: filgrastim) is a growth factor that affects the hematopoietic system, promoting differentiation, proliferation, and survival of granulocytes⁶. Clinically, in Japan, G-CSF is administered to patients with leukopenia, and to peripheral stem cell transplantation donors, G-CSF is administered to mobilize hematopoietic stem cells into the peripheral blood⁷. In the central nervous system, G-CSF has properties to mobilize the movement of bone marrow cells into the brain⁸ and spine, and in a stroke model, has shown neuroprotective properties⁹. In other countries, clinical studies of the effects of G-CSF in cerebral infarction have been reported¹⁰.

To prove the hypothesis that G-CSF has neuroprotective properties against SCI, G-CSF was administered to rat and mouse animal models of spinal cord injury, and hind limb

BMJ Open: first published as 10.1136/bmjopen-2017-019083 on 5 May 2018. Downloaded from http://bmjopen.bmj.com/ on March 3, 2023 by guest. Protected by copyright

function improved significantly after administration of G-CSF. Further investigations into the mechanism of action of G-CSF in SCI were conducted. Data obtained to date identify the following properties of G-CSF: [1] mobilization of bone marrow-derived stem cells causing their biointegration at the site of SCI¹¹, [2] direct inhibition of nerve cell death¹², [3] protection of the myelin sheath by inhibiting oligodendrocyte cell death¹³, [4] inhibition of inflammatory cytokine expression (TNF- α , IL-1 β)¹³, and [5] promotion of neovascularization¹⁴. These properties suggest that G-CSF has a neuroprotective effect in acute SCI.

Based on these properties, a phase 1/2a clinical study was conducted where the main objective was to confirm the safety and feasibility of G-CSF for treatment of patients with acute SCI¹⁵. This study was an open-label, dose-titrating study with no control group. As the initial step, 5 patients were given 5 μ g/kg/day of G-CSF for 5 consecutive days by i.v. infusion, and as the second step, 11 patients were given 10 μ g/kg/day of G-CSF for 5 consecutive days by i.v. infusion. No serious adverse events were noted, and the safety of G-CSF administration in patients with acute SCI was confirmed¹⁵.

As a next step, to validate the efficacy of G-CSF in neuroprotective treatment, a multicenter, prospective, nonrandomized, nonblinded, comparative control study (phase 2b clinical trial) was conducted¹⁶. Based on the results of the previous phase 1/2a clinical trial, the dosage and duration of treatment with G-CSF in this study was 10 μ g/kg/day for 5 consecutive days. Patients with acute cervical SCI (within 48 h of injury) were registered in the clinical trial and allocated to either the G-CSF group (G-CSF 10 μ g/kg/day × 5 days i.v. infusion) or control group (no G-CSF administration) at each treatment facility. A total of 19 patients in the G-CSF group and 26 patients in the control group were observed for 3 months or longer. American Spinal Injury Association (ASIA) motor score (motor: 0 to 100 points) was compared between the groups. ASIA motor scores were 26.1 ± 18.9 in the G-CSF group and 12.2 ± 14.7 in the control group showing a significant improvement of motor paralysis in the G-CSF group (p < 0.01). In addition, in cases that could be followed for 1 year or longer, a significant improvement of ASIA motor score was observed in the G-CSF group¹⁶.

BMJ Open

Specific Objective

The objective of this study is to prove the efficacy of G-CSF for improving motor paralysis in acute SCI.

Methods and Analysis

Design of the study

The study design of the current trial is a prospective, multicenter, randomized, double-blinded, placebo-controlled comparative study.

Study Procedures

Patients will be randomly assigned to G-CSF and placebo groups. A central registration system will be used for dynamic randomization into the investigational treatment group (G-CSF) and control group (placebo) based on age at registration (16–64 years of age, or 65–84 years of age) and severity of paralysis (AIS B or C) at 48 h after injury. Each subject will be randomly allocated to either the investigational treatment group (G-CSF) or control group (placebo) in a 1 to 1 ratio. The subject registration center uses a program based on an appropriate computer algorithm to allocate patients into groups.

The G-CSF group will be administered 400 μ g/m²/d × 5d of G-CSF in normal saline via intravenous infusion for 5 consecutive days. The placebo group will be similarly administered a placebo. Allocation will be concealed between blinded evaluators of efficacy/safety and those for laboratory data, as G-CSF markedly increases white blood cell counts that can reveal patient treatment.

Our primary endpoint is changes in ASIA motor scores from baseline to 3 months calculated as follows: 3-month ASIA motor score change = 3-month ASIA motor score – pretreatment ASIA motor score.

Secondary endpoints are as follows. [1] Change in ASIA motor scores at 6 months and 12 months after G-CSF administration compared with pretreatment. [2] Changes in sensory

BMJ Open: first published as 10.1136/bmjopen-2017-019083 on 5 May 2018. Downloaded from http://bmjopen.bmj.com/ on March 3, 2023 by guest. Protected by copyright

paralysis over time: change in ASIA sensory scores at 3 months, 6 months, and 12 months after G-CSF administration compared with pretreatment. [3] Severity of functional compromise because of paralysis: AIS before administration and at 3, 6, and 12 months after administration of G-CSF. [4] Percentage of responders: percentage of patients whose AIS improved by 1 grade or more at 3, 6, and 12 months after administration compared with before administration of G-CSF. [5] Neurological level of injury (NLI): percentage of patients whose NLI decreased by 1 grade of more at 3, 6, or 12 months after administration of G-CSF compared with pretreatment. [6] SCIM: change in ASIA motor scores at 3, 6, and 12 months after G-CSF administration compared with pretreatment [7] EQ-5D: measured EQ-5D efficacy scores at 3, 6, and 12 months after G-CSF.

Each group will include 44 patients (88 patients in total). Our protocol was approved by the Pharmaceuticals and Medical Device Agency and this trial will be funded by the Center for Clinical Trials, Japan Medical Association.

Inclusion

Inclusion criteria are as follows. [1] Patients with cervical SCI (severity of AIS B/C) within 48 h of injury. [2] Patients reassessed for neurological status at 48 h after injury, and those whose palsy is AIS B/C will be enrolled. [3] Patients with neurological level of injury between C4 and C7. [4] Patients with age of 16 to 85 years. [5] Patients who agree to participate in the current trial and from whom informed consent was obtained orally and in writing. [6] Patients who can be followed up for 12 months after SCI.

Exclusion

Exclusion criteria are as follows. [1] Patients with neurological recovery to AIS D at neurological reassessment 48 h after SCI, because only AIS B/C patients will be included to standardize the severity of paresis in order to stratify the patients at the initiation of drug administration. [2] Allergy to G-CSF. [3] Hematological malignancy, [4] within 6 months after invasive coronary intervention, [5] splenomegaly, or [6] pregnancy, [7] neurological disorders that can affect neurological evaluation in the present trial, [8] fracture of

extremities that can affect the neurological evaluation. Exclusion criteria 2 - 6 are set for safety and criteria 1, 7 and 8 are set to maintain homogeneity of the patient population enrolled.

Concealment

Patients will be administered drug or placebo and be evaluated in a double-blinded manner. An evaluator blinded to the treatment will take charge of patient evaluation including clinical findings and paresis, without laboratory data because G-CSF induces an apparent increase of white blood cell count that makes it easy to distinguish G-CSF and placebo treatment. Therefore, a non-blinded evaluator for laboratory data will be assigned to evaluate laboratory data alone. From a safety point-of view, the dose of G-CSF will be modulated according to excessive increase of white blood cell count as shown in Table 2. Therefore, a non-blinded evaluator will instruct the pharmacy to modulate the dose of G-CSF based on white blood cell count.

Sample Size Calculation

The target sample size for this randomized trial is 88. This number is based on the results of previous clinical trials¹⁶. The estimated group difference (\pm standard deviation) of change in ASIA motor scores from baseline to 3 months is 13.9 (\pm 21.9). A sample size of 44 patients in each group will provide 80% power to detect a difference of the change in ASIA motor scores between the G-CSF and the placebo treatments, using a mixed-effects models for repeated measures (MMRM) at a two-sided 5% level of significance. A common correlation of 0.25 at each time point is assumed. A dropout rate of 10% is allowed. Thus, the total sample size of 88 patients is required for the trial.

BMJ Open: first published as 10.1136/bmjopen-2017-019083 on 5 May 2018. Downloaded from http://bmjopen.bmj.com/ on March 3, 2023 by guest. Protected by copyright

Statistical analyses

The analyses of the primary and secondary end points will be performed in a full analysis set, which includes all patients who: (1) took at least one course of treatment during the study; (2) do not present any serious violation of the study protocol; and (3) have

BMJ Open: first published as 10.1136/bmjopen-2017-019083 on 5 May 2018. Downloaded from http://bmjopen.bmj.com/ on March 3, 2023 by guest. Protected by copyright

data collected after commencement of treatment. For the baseline characteristics, summary statistics will comprise frequencies and proportions for categorical variables, and means and SDs for continuous variables. The patient characteristics will be compared using a chi-square test for categorical variables, and a *t* test or Wilcoxon rank sum test for continuous variables.

For the primary analysis, aimed at comparing treatment effects, a change in ASIA motor score from baseline to 3 months and its 95% confidence interval (CI) will be estimated using the MMRM. To test for significant association of the primary endpoint, a mixed effects model for repeated measures with an unstructured covariance matrix will be applied to adjust for age (<65 years or \geq 65 years) and AIS at 48 h after the injury (B or C).

For the secondary analysis, the change in ASIA motor score will be compared using a Student *t* test and the 95% CI will be estimated. The same method will be applied to change in sensory score, SCIM, and EQ-5D. A chi-squared test will be applied to the frequencies of the responder in AIS and of the improvement in NLI. The frequency of AIS will be summarized. The frequency of AEs will be compared using a Fisher exact test.

All comparisons are planned and all p values will be two sided. p < 0.05 will be considered significant. All statistical analyses will be performed using SAS software (version 9.4; SAS Institute, Cary, NC, USA). The statistical analysis plan will be developed by the principal investigator and the biostatistician before completion of patient recruitment and fixing of data.

Data Monitoring Committee

The data monitoring committee consists of three clinical trial specialists, including a biostatistician, who are independent from the current study. The committee will meet at least 2 times per year and all the data obtained by the current trial will be checked by the committee.

Adverse Events

As for safety evaluation, adverse events will be collected as follows. "Adverse events"

BMJ Open

refers to any untoward symptom or disease or signs of such (including clinical laboratory data abnormalities) in a clinical investigation subject after informed consent and does not necessarily have a causal relationship with the investigational product (G-CSF).

Increases in white blood counts will be considered an adverse event only when the count exceeds $50,000/\mu$ L from the perspective of a pharmacological effect of G-CSF, and any values below this will not be handled as an adverse event.

All adverse events will code terminology used by the investigators according to the ICH International Medical Dictionary for Regulatory Activities Japanese version (MedDRA/J).

Ethics and Dissemination

Ethics

The study was approved by the Institutional Review Board (IRB) of each institutions involved to the present trial and will be conducted according to the principles of the World Medical Association (WMA) Declaration of Helsinki—Ethical Principles for Medical Research Involving Human Subjects with the amendments made in Seoul, South Korea, October 2008, with a Note of Clarification on Paragraph 29 added by the WMA General Assembly, Washington 2002; Note of Clarification on Paragraph 30 added by the WMA General Assembly, Tokyo 2004, and in accordance with the Japanese Medical Research Involving Human Subjects Act (WMO) and other guidelines, regulations and Acts. *Public Disclosure and Publication Policy*

Results of the clinical study will be submitted to the head of the respective clinical study site as a report after conclusion of the clinical study by the sponsor-investigator (includes study coordinating investigator). Even if the results are not favorable despite conducting the clinical study properly, the data will be published as a paper. Other sponsor-investigators (including the clinical study coordinating investigator), if they plan to publicize the data from this study in a specialized academic society conference or other external site, must first obtain permission from the other principal investigators and investigational product provider. In publicizing the results, the confidentiality of the subjects will be maintained and proofread in advance by the other sponsor-investigators

(includes coordinating investigator) and investigational product provider.

Discussion

The current trial is a confirmative trial to elucidate the therapeutic efficacy of G-CSF for SCI. If the current trial can successfully show significant improvement of motor paralysis of SCI by G-CSF, we will move forward to drug approval application to the Ministry for Health and Labor, Japan. The entire protocol of the current trial was approved beforehand for the initiation of the current trial by the Japanese Pharmaceutical and Medical Device Agency (PMDA). The PMDA will also permit a drug approval application if significant efficacy of G-CSF for SCI is proven.

The current trial is an important milestone for SCI clinics and research to explore G-CSF for SCI. ing.

Trial Status

The present trial is now on-going.

Trial Sites

Nineteen major hospitals in Japan constituting the G-SPIRIT study group as follows: Tohoku University Hospital, Miyagi; Niigata University, Niigata; Dokkyo University Hospital, Tochigi; Tsukuba University Hospital, Ibaraki; Tsukuba Medical Center, Ibaraki; Chiba University Hospital, Chiba; Funabashi Municipal Medical Center, Chiba; Kimitsu Chuo Hospital, Chiba; Chiba Rosai Hospital, Chiba; Tokai University Hospital, Kanagawa; Hamamatsu University Hospital, Shizuoka; Gifu University Hospital, Gifu; Chubu Rosai Hospital, Aichi; Mie University Hospital, Mie; Kanazawa Medical Collage, Ishikawa; Kobe Red Cross Hospital, Hyogo; Hiroshima University Hospital, Hiroshima; Yamaguchi University Hospital, Yamaguchi; and Nagasaki Rosai Hospital, Nagasaki.

Funding Statement

This trial is supported by Center for Clinical trials, Japan Medical Association, Japan.

No authors have any competing interests to declare.

Contributorship Statement

MK, TF and MY contributed to planning and conduct of the present trial and to reporting the present protocol paper. HH, TS, YF, MH and ST contributed to conception and design of the present trial protocol and to reporting the present protocol paper. YI, JS, MK, SO, YM, TA, KW, TH, MO, HS, TM, IT, NK, MK. YO, TS, MY, MF, KY, DS, HT, DT, SI, HM, HU, FA, YS, IA, YT, MM, JS, YS, SI, HS, KT, YI, FN, MH, TO, FH, TF, KK, MW, HK, YM, YY, DT, TH, SK, GY, SO, TB, HA, KA, EK, HI, TS, AS, YI, TK, SO, NT, KN, NK, SK, HB, TO, HK, TY, IK, KY, TM, TM, IM, HK, TA, KH, TE, TS, MM, KF, SN, CI, TT, TK, HS, NN and MF contributed to conducting the present trial and to acquisition of data.

CONSORT 2010 checklist of information to include when reporting a randomised trial*

Section/Topic	ltem No	Checklist item	Reported on page No
Title and abstract			
	1a	Identification as a randomised trial in the title	1
	1b	Structured summary of trial design, methods, results, and conclusions (for specific guidance see CONSORT for abstracts)	3
Introduction			
Background and	2a	Scientific background and explanation of rationale	4-5
objectives	2b	Specific objectives or hypotheses	6
Methods			
Trial design	3a	Description of trial design (such as parallel, factorial) including allocation ratio	6
Ū	3b	Important changes to methods after trial commencement (such as eligibility criteria), with reasons	N/A
Participants	4a	Eligibility criteria for participants	7
	4b	Settings and locations where the data were collected	11
Interventions	5	The interventions for each group with sufficient details to allow replication, including how and when they were actually administered	6-7
Outcomes	6a	Completely defined pre-specified primary and secondary outcome measures, including how and when they were assessed	6-7
	6b	Any changes to trial outcomes after the trial commenced, with reasons	N/A
Sample size	7a	How sample size was determined	8
Randomisation:	7b	When applicable, explanation of any interim analyses and stopping guidelines	N/A
Sequence	8a	Method used to generate the random allocation sequence	6
generation	8b	Type of randomisation; details of any restriction (such as blocking and block size)	6
Allocation	9	Mechanism used to implement the random allocation sequence (such as sequentially numbered containers),	8
concealment mechanism		describing any steps taken to conceal the sequence until interventions were assigned	
Implementation	10	Who generated the random allocation sequence, who enrolled participants, and who assigned participants to interventions	6
Blinding	11a	If done, who was blinded after assignment to interventions (for example, participants, care providers, those	8

Abstract

Introduction: Granulocyte Colony Stimulating Factor (G-CSF) is generally used for neutropenia. Previous experimental studies revealed that G-CSF promoted neurological recovery after spinal cord injury (SCI). Next we moved to early phase of clinical trials. In a phase 1/2a trial, no adverse events were observed. Next, we conducted a non-randomized, non-blinded, comparative trial, which suggested the efficacy of G-CSF for promoting neurological recovery. Based on those results, we are now performing a phase 3 trial. Methods and Analysis: The objective of this study is to evaluate the efficacy of G-CSF for acute SCI. The study design is a prospective, multicenter, randomized, double-blinded, placebo-controlled comparative study. The current trial includes cervical SCI (severity of American Spinal Injury Association (ASIA) Impairment Scale B/C) within 48 hours after injury. Patients are randomly assigned to G-CSF and placebo groups. The G-CSF group is administered 400 μ g/m²/d×5d of G-CSF in normal saline via intravenous infusion for 5 consecutive days. The placebo group is similarly administered a placebo. Our primary endpoint is changes in ASIA motor scores from baseline to 3 months. Each group includes 44 patients (88 total patients). This trial is funded by the Center for Clinical Trials, Japan Medical Association.

Ethics and Dissemination: The study was approved by the Institutional Review Board of each institution and will be conducted according to the principles of the World Medical Association Declaration of Helsinki and in accordance with the Japanese Medical Research Involving Human Subjects Act and other guidelines, regulations and Acts. Results of the clinical study will be submitted to the head of the respective clinical study site as a report after conclusion of the clinical study by the sponsor-investigator. Even if the results are not favorable despite conducting the clinical study properly, the data will be published as a paper.

Strengths and Limitations of This Study

Strengths

- ✓ Novel drug therapy for acute spinal cord injury is much-needed.
- ✓ Randomized, placebo-controlled, double-blinded design can eliminate bias.

Limitations

- \checkmark Acute spinal cord injury patients are difficult to recruit to the trial.
- Patient's neurological status in acute phase is unstable, possibly resulting in dispersion of the patient's background.
- ✓ Concealment must be performed very strictly because G-CSF apparently increases

white blood cell count.

Introduction

Spinal cord injury (SCI) is a devastating injury by which the patient can suffer from long-lasting severe sequelae including palsy of extremities, sensory disturbance, bowel/bladder/sexual dysfunction, and neuropathic pain. Conceptually, SCI is divided into two chronological phases: a primary and a secondary phase. Primary injury is mechanical damage to spinal cord tissue itself caused by fracture and/or dislocation or compression. Secondary injury is triggered by the primary injury and is a biological reaction of the spinal cord, which includes ischemia, hemorrhage, excitotoxicity, hyperpermeability, and inflammation¹. Because secondary injury can be the main target of treatment, extensive laboratory and clinical investigation of neuroprotection is needed to manage secondary injury².

To date, the only approved neuroprotective therapy for SCI is massive methylprednisolone sodium succinate (MPSS) therapy based on the NASCIS 2 study³. However, recent reports revealed that MPSS shows only a modest effect for SCI. In addition, several reports have described adverse events induced by MPSS for SCI including infections (pneumonia, urinary tract infection) and gastrointestinal disorders (gastric ulcer, etc.)⁴. Therefore, the use of MPSS for SCI has become controversial⁵. Accordingly, a new therapeutic drug for SCI is desirable. BMJ Open: first published as 10.1136/bmjopen-2017-019083 on 5 May 2018. Granulocyte colony-stimulating factor (G-CSF, generic name: filgrastim) is a growth factor that affects the hematopoietic system, promoting differentiation, proliferation, and survival of granulocytes⁶. Clinically, in Japan, G-CSF is administered to patients with leukopenia, and to peripheral stem cell transplantation donors, G-CSF is administered to mobilize hematopoietic stem cells into the peripheral blood⁷. In the central nervous system, G-CSF has properties to mobilize the movement of bone marrow cells into the brain⁸ and spine, and in a stroke model, has shown neuroprotective properties⁹. In other countries, clinical studies of the effects of G-CSF in cerebral infarction have been reported¹⁰.

To prove the hypothesis that G-CSF has neuroprotective properties against SCI, G-CSF was administered to rat and mouse animal models of spinal cord injury, and hind limb

BMJ Open: first published as 10.1136/bmjopen-2017-019083 on 5 May 2018. Downloaded from http://bmjopen.bmj.com/ on March 3, 2023 by guest. Protected by copyright

function improved significantly after administration of G-CSF. Further investigations into the mechanism of action of G-CSF in SCI were conducted. Data obtained to date identify the following properties of G-CSF: [1] mobilization of bone marrow-derived stem cells causing their biointegration at the site of SCI¹¹, [2] direct inhibition of nerve cell death¹², [3] protection of the myelin sheath by inhibiting oligodendrocyte cell death¹³, [4] inhibition of inflammatory cytokine expression (TNF- α , IL-1 β)¹³, and [5] promotion of neovascularization¹⁴. These properties suggest that G-CSF has a neuroprotective effect in acute SCI.

Based on these properties, a phase 1/2a clinical study was conducted where the main objective was to confirm the safety and feasibility of G-CSF for treatment of patients with acute SCI¹⁵. This study was an open-label, dose-titrating study with no control group. As the initial step, 5 patients were given 5 μ g/kg/day of G-CSF for 5 consecutive days by i.v. infusion, and as the second step, 11 patients were given 10 μ g/kg/day of G-CSF for 5 consecutive days by i.v. infusion. No serious adverse events were noted, and the safety of G-CSF administration in patients with acute SCI was confirmed¹⁵.

As a next step, to validate the efficacy of G-CSF in neuroprotective treatment, a multicenter, prospective, nonrandomized, nonblinded, comparative control study (phase 2b clinical trial) was conducted¹⁶. Based on the results of the previous phase 1/2a clinical trial, the dosage and duration of treatment with G-CSF in this study was 10 μ g/kg/day for 5 consecutive days. Patients with acute cervical SCI (within 48 h of injury) were registered in the clinical trial and allocated to either the G-CSF group (G-CSF 10 μ g/kg/day × 5 days i.v. infusion) or control group (no G-CSF administration) at each treatment facility. A total of 19 patients in the G-CSF group and 26 patients in the control group were observed for 3 months or longer. American Spinal Injury Association (ASIA) motor score (motor: 0 to 100 points) was compared between the groups. ASIA motor scores were 26.1 ± 18.9 in the G-CSF group and 12.2 ± 14.7 in the control group showing a significant improvement of motor paralysis in the G-CSF group (p < 0.01). In addition, in cases that could be followed for 1 year or longer, a significant improvement of ASIA motor score was observed in the G-CSF group¹⁶.

BMJ Open

Based on results of these preclinical and early phase clinical trials, we are now conducting a phase 3 trial.

Specific Objective

The objective of this study is to evaluate the efficacy of G-CSF for improving motor paralysis in acute SCI.

Methods and Analysis

Design of the study

The study design of the current trial is a prospective, multicenter, randomized, double-blinded, placebo-controlled comparative study.

Study Procedures

The study outline is shown in Figure. Patients will be randomly assigned to G-CSF and placebo groups. A central registration system will be used for dynamic randomization into the investigational treatment group (G-CSF) and control group (placebo) based on age at registration (16–64 years of age, or 65–84 years of age) and severity of paralysis (AIS B or C) at 48 h after injury. Initially, screened patients with severity AIS B/C will be tentatively enrolled. Initial screening of the patients include clinical laboratory test, imaging studies including X-ray, magnetic resonance imaging and computed tomography, and neurological/functional evaluations.

Neurological re-assessment will be performed 48±4 hours after SCI and the patients who will recover to severity AIS D will be excluded. The patients with severity AIS B/C at neurological re-assessment 48±4 hours after SCI will be enrolled and randomly allocated to either the investigational treatment group (G-CSF) or control group (placebo) in a 1 to 1 ratio. The subject registration center uses a program based on an appropriate computer algorithm to allocate patients into groups. The first dose of investigative drugs will be administered to the patients after re-assessment of neurological status and enrollment 48±4 hours after SCI.

BMJ Open: first published as 10.1136/bmjopen-2017-019083 on 5 May 2018. Downloaded from http://bmjopen.bmj.com/ on March 3, 2023 by guest. Protected by copyright

The G-CSF group will be administered 400 μ g/m²/d × 5d of G-CSF in normal saline via intravenous infusion for 5 consecutive days. The placebo group will be similarly administered a placebo. The first dose of investigative drugs will be administered to the patients 48±4 hours after SCI. The dosing schedule will be once a day in every morning (9-10 AM) for consecutive 5 days even in case that the first dosing was performed at night because of restriction on practices. Investigational drugs including both G-CSF and placebo will be stored in refrigerator which will be kept between 1- 6 \Box and has temperature-logger in pharmacies in each participating institutes. The investigational drugs is packaged in ample with label only printed as serial numbers, ten ample is packed in one box with label only printed serial numbers. Web-based allocation system will show the serial number of investigational drug which must be used to respective patients to ensure blinding.

We decided dosage of drug based on our previous non-randomized early phase clinical studies. On phase 1/2a clinical study, of which study design was open-label, dose-titrating study with no control group, SCI patients who were administered 10 μ g/kg/day G-CSF for 5 days showed marked elevation of white blood cell number (reached nearly 50000/ μ l, of which WBC number might cause adverse effects of G-CSF) during G-CSF administration¹⁵. Therefore we decided to withdraw additional titration. In addition, next phase of clinical study, of which design was multicenter, prospective, nonrandomized, nonblinded, comparative control study, showed suggestive efficacy of G-CSF (10 μ g/kg/d for 5 days) for acute SCI¹⁶. Based on those results, we finally decided the dosage of G-CSF as 10 μ g/kg/d × 5d for 5 days. In the current clinical trial, the dosage of G-CSF is written as 400 μ g/m²/d (= 10 μ g/kg/d) according to the Japanese Pharmaceutical and Medical Device Agency (PMDA)'s instruction for consolidation with product labeling.

We decided to 48hours after SCI as the therapeutic time window because our previous multicenter, prospective, nonrandomized, nonblinded, comparative control study, which recruited SCI patients within 48 hours after injury, showed that there was no significant difference in neurological outcome between the patient administered G-CSF very early after the injury and 48 hours after injury¹⁶.

Allocation will be concealed between blinded evaluators of efficacy/safety and those

For peer review only - http://bmjopen.bmj.com/site/about/guidelines.xhtml

BMJ Open

for laboratory data, as G-CSF markedly increases white blood cell counts that can reveal patient treatment.

Our primary endpoint is changes in ASIA motor scores (international standards for neurological classification of spinal cord injury (ISNSCI) suppl. Figure 1) from baseline to 3 months calculated as follows: 3-month ASIA motor score change = 3-month ASIA motor score – pretreatment ASIA motor score. To maintain consistency of neurological assessment among the each evaluators, attending lecture and e-learning (in website of International Spinal Cord Society: http://www.elearnsci.org/) of ASIA/ISNSCI scoring system is mandatory for every investigators participating to the present trial.

Secondary endpoints are as follows. [1] Change in ASIA motor scores at 6 months and 12 months after G-CSF administration compared with pretreatment. [2] Changes in sensory paralysis over time: change in ASIA sensory scores at 3 months, 6 months, and 12 months after G-CSF administration compared with pretreatment. [3] Severity of functional compromise because of paralysis: AIS before administration and at 3, 6, and 12 months after administration of G-CSF. [4] Percentage of responders: percentage of patients whose AIS improved by 1 grade or more at 3, 6, and 12 months after administration compared with before administration compared with before administration of G-CSF. [5] Neurological level of injury (NLI): percentage of patients whose NLI decreased by 1 grade of more at 3, 6, or 12 months after administration of G-CSF compared with pretreatment. [6] SCIM: change in SCIM scores at 3, 6, and 12 months after G-CSF administration compared with pretreatment [7] EQ-5D: measured EQ-5D efficacy scores at 3, 6, and 12 months after G-CSF.

To strengthen the analysis, more strict blindness of assessment by the evaluator for outcome measures is ideal. Therefore every prior score/measurement should be blinded and/or not the same person should assess every midpoint motor/sensory functional measurement. However, PMDA instructed us to assess one patients' functional evaluation by one evaluator for consistent assessment in respective patients. PMDA considers the consistency of assessment in respective patients is more important.

The precise explanation of abovementioned outcome measures is as followings (suppl. Figures). ASIA motor score is determined by examining a key muscle function within each

BMJ Open: first published as 10.1136/bmjopen-2017-019083 on 5 May 2018. Downloaded from http://bmjopen.bmj.com/ on March 3, 2023 by guest. Protected by copyright

of 10 myotomes on each side of the body on manual muscle testing (MMT) in the supine position. There is a range of score from 0 to 25 for each extremity, totaling 0 to 50 for the upper limbs and 0 to 50 for the lower limbs, resulting in total of ASIA motor score ranges from 0 to 100. This score can reflect the degree of motor impairment associated with the SCI (suppl. Figure 1). ASIA sensory scores is completed through the testing of a key point in each of the 28 dermatomes (from C2 to S4-5) on the right and left sides of the body that can be readily located in relation to bony anatomical landmarks. At each of these key points, two aspects of sensation are examined: light touch and pin prick. Appreciation of light touch and pin prick sensation at each of the key points is separately scored on a three-point scale, with comparison to the sensation on the patients' cheek as a normal frame of reference: 0 = absent, 1 = altered, 2 = normal or intact. As a result, ASIA sensory scores range from 0 to 112 (suppl. Figure 1). AIS designation is used in grading the degree of impairment: A = Complete. No sensory or motor function is preserved in the sacral segments S4-S5. B = Sensory incomplete. Sensory but not motor function is preserved below the neurological level. C = Motor incomplete. Motor function is preserved below the neurological level, and more than half of key muscle functions below the single neurological level of injury have a muscle grade less than 3 (Grades 0-2). D = Motor incomplete. Motor function is preserved below the neurological level, and at least half (half or more) of key muscle functions below the neurological level have a muscle grade >3. E = Normal. If sensation and motor function as tested are graded as normal in all segments, and the patient had prior deficits, then the AIS grade is E (suppl. Figure 1, footnote). NLI refers to the most caudal segment of the cord with intact sensation and antigravity muscle function strength, provided that there is normal (intact) sensory and motor function rostrally (suppl. Figure 1, footnote). SCIM is disability scale developed specifically for patients with spinal cord lesions in order to make the functional assessments of patients with paraplegia or tetraplegia more sensitive to changes. The SCIM includes the following areas of function: self-care (subscore (0-20), respiration and sphincter management (0-40) and mobility (0-40). Each area is scored according to its proportional weight in these patients' general activity. The final score ranges from 0 to 100 (suppl. Figure 2-4). EQ-5D

essentially consists of 2 pages (suppl. Figure 5, 6): the EQ-5D descriptive system and the EQ visual analogue scale (EQ VAS). The descriptive system comprises five dimensions: mobility, self-care, usual activities, pain/discomfort and anxiety/depression. Each dimension has 5 levels: no problems, slight problems, moderate problems, severe problems and extreme problems. The patient is asked to indicate his/her health state by ticking the box next to the most appropriate statement in each of the five dimension. This decision results in a 1-digit number that expresses the level selected for that dimension. The digits for the five dimensions can be combined into a 5-digit number that describes the patient's health state and can be converted to efficacy score with calibration scale (ranges -0.111 to 1.000). The EQ VAS records the patient's self-rated health on a vertical visual analogue scale, where the endpoints are labelled 'The best health you can imagine'. The VAS can be used as a quantitative measure of health outcome that reflect the patient's own judgement.

Each group will include 44 patients (88 patients in total). Our protocol was approved by PMDA and this trial will be funded by the Center for Clinical Trials, Japan Medical Association.

BMJ Open: first published as 10.1136/bmjopen-2017-019083 on 5 May 2018. Downloaded from http://bmjopen.bmj.com/ on March 3, 2023 by guest. Protected by copyright

Inclusion

Inclusion criteria are as follows. [1] Patients with cervical SCI (severity of AIS B/C) within 48 h of injury. [2] Patients reassessed for neurological status at 48 h after injury, and those whose palsy is AIS B/C will be enrolled. [3] Patients with neurological level of injury between C4 and C7. [4] Patients with age of 16 to 85 years. [5] Patients who agree to participate in the current trial and from whom informed consent was obtained orally and in writing. [6] Patients who can be followed up for 12 months after SCI.

Exclusion

Exclusion criteria are as follows. [1] Patients with neurological recovery to AIS D at neurological reassessment 48 h after SCI, because only AIS B/C patients will be included to

standardize the severity of paresis in order to stratify the patients at the initiation of drug administration. [2] Allergy to G-CSF. [3] Hematological malignancy, [4] within 6 months after invasive coronary intervention, [5] splenomegaly, or [6] pregnancy, [7] consciousness impairment, [8] neurological disorders that can affect neurological evaluation in the present trial, [9] fracture of extremities that can affect the neurological evaluation and [10] massive dose administration of MPSS. Exclusion criteria 2 - 6 are set for safety, criteria 1, 7 - 9 are set to maintain homogeneity of the patient population enrolled, criteria 7-9 are set for maintenance of accuracy of functional assessment, criteria 7 is set to obtain patients' own informed consent upon participation to the trial and criteria 10 is set to omit the possible interference of MPSS on outcome assessment.

Concealment

Patients will be administered drug or placebo and be evaluated in a double-blinded manner. An evaluator blinded to the treatment will take charge of patient evaluation including clinical findings and paresis, without laboratory data because G-CSF induces an apparent increase of white blood cell count that makes it easy to distinguish G-CSF and placebo treatment. Therefore, a non-blinded evaluator for laboratory data will be assigned to evaluate laboratory data alone. From a safety point-of view, the dose of G-CSF will be modulated according to excessive increase of white blood cell count. Therefore, a non-blinded evaluator will instruct the pharmacy to modulate the dose of G-CSF based on white blood cell count.

Sample Size Calculation

The target sample size for this randomized trial is 88. This number is based on the results of previous clinical trials¹⁶. The estimated group difference (\pm standard deviation) of change in ASIA motor scores from baseline to 3 months is 13.9 (\pm 21.9). A sample size of 44 patients in each group will provide 80% power to detect a difference of the change in ASIA motor scores between the G-CSF and the placebo treatments, using a mixed-effects models for repeated measures (MMRM) at a two-sided 5% level of significance. A

BMJ Open: first published as 10.1136/bmjopen-2017-019083 on 5 May 2018. Downloaded from http://bmjopen.bmj.com/ on March 3, 2023 by guest. Protected by copyright

BMJ Open

common correlation of 0.25 at each time point is assumed. A dropout rate of 10% is allowed. Thus, the total sample size of 88 patients is required for the trial.

Statistical analyses

The analyses of the primary and secondary end points will be performed as intention-to-treat analyses in a full analysis set, which includes all patients who: (1) took at least one course of treatment during the study; (2) do not present any serious violation of the study protocol; and (3) have data collected after commencement of treatment. For the baseline characteristics, summary statistics will comprise frequencies and proportions for categorical variables, and means and SDs for continuous variables. The patient characteristics will be compared using a chi-square test for categorical variables, and a *t* test or Wilcoxon rank sum test for continuous variables. Missing data including loss to follow-up and missing measurement will be supplemented with MMRM.

For the primary analysis, aimed at comparing treatment effects, a change in ASIA motor score from baseline to 3 months and its 95% confidence interval (CI) will be estimated using the MMRM. To test for significant association of the primary endpoint, a mixed effects model for repeated measures with an unstructured covariance matrix will be applied to adjust for age (<65 years or \geq 65 years) and AIS at 48 h after the injury (B or C).

For the secondary analysis, the change in ASIA motor score will be compared using a Student *t* test and the 95% CI will be estimated. The same method will be applied to change in sensory score, SCIM, and EQ-5D. A chi-squared test will be applied to the frequencies of the responder in AIS and of the improvement in NLI. The frequency of AIS will be summarized. The frequency of AEs will be compared using a Fisher exact test.

All comparisons are planned and all p values will be two sided. p < 0.05 will be considered significant. All statistical analyses will be performed using SAS software (version 9.4; SAS Institute, Cary, NC, USA). The statistical analysis plan will be developed by the principal investigator and the biostatistician before completion of patient recruitment and fixing of data.

BMJ Open: first published as 10.1136/bmjopen-2017-019083 on 5 May 2018. Downloaded from http://bmjopen.bmj.com/ on March 3, 2023 by guest. Protected by copyright

Data Monitoring Committee

The data monitoring committee consists of three clinical trial specialists, including a biostatistician, who are independent from the current study. The committee will meet at least 2 times per year and all the data obtained by the current trial will be checked by the committee.

Adverse Events

As for safety evaluation, adverse events will be collected as follows. "Adverse events" refers to any untoward symptom or disease or signs of such (including clinical laboratory data abnormalities) in a clinical investigation subject after informed consent and does not necessarily have a causal relationship with the investigational product (G-CSF).

Increases in white blood counts will be considered an adverse event only when the count exceeds $50,000/\mu$ L from the perspective of a pharmacological effect of G-CSF, and any values below this will not be handled as an adverse event. Anaphylaxis and adult respiratory distress syndrome are the most representative G-CSF-related severe adverse events to be payed full attention.

All adverse events will code terminology used by the investigators according to the ICH International Medical Dictionary for Regulatory Activities Japanese version (MedDRA/J).

Ethics and Dissemination

Ethics

The study was approved by the Institutional Review Board (IRB) of each institutions involved to the present trial and will be conducted according to the principles of the World Medical Association (WMA) Declaration of Helsinki—Ethical Principles for Medical Research Involving Human Subjects with the amendments made in Seoul, South Korea, October 2008, with a Note of Clarification on Paragraph 29 added by the WMA General Assembly, Washington 2002; Note of Clarification on Paragraph 30 added by the WMA General Assembly, Tokyo 2004, and in accordance with the Japanese Medical Research Involving Human Subjects Act (WMO) and other guidelines, regulations and Acts.

Patient informed consent

The principal investigator will try to prepare the informed consent form and other explanatory materials in as simple language as possible in order to obtain informed consent from the patient and the patient's legal representative. In case that trial participants cannot sign the informed consent form due to upper extremity palsy caused by SCI, allograph by patients' representative will be allowed.

Public Disclosure and Publication Policy

Results of the clinical study will be submitted to the head of the respective clinical study site as a report after conclusion of the clinical study by the sponsor-investigator (includes study coordinating investigator). Even if the results are not favorable despite conducting the clinical study properly, the data will be published as a paper. Other sponsor-investigators (including the clinical study coordinating investigator), if they plan to publicize the data from this study in a specialized academic society conference or other external site, must first obtain permission from the other principal investigators and investigational product provider. In publicizing the results, the confidentiality of the subjects will be maintained and proofread in advance by the other sponsor-investigators (includes coordinating investigator) and investigational product provider.

Discussion

The current trial is a confirmative trial to elucidate the therapeutic efficacy of G-CSF for SCI. If the current trial can successfully show significant improvement of motor paralysis of SCI by G-CSF, we will move forward to drug approval application to the Ministry for Health and Labor, Japan. The entire protocol of the current trial was approved beforehand for the initiation of the current trial by the Japanese Pharmaceutical and Medical Device Agency (PMDA). The PMDA will also permit a drug approval application if significant efficacy of G-CSF for SCI is proven.

The current trial is an important milestone for SCI clinics and research to explore

G-CSF for SCI.

Trial Status

The present trial is now on-going.

Trial Sites

Nineteen major hospitals in Japan constituting the G-SPIRIT study group as follows: Tohoku University Hospital, Miyagi; Niigata University, Niigata; Dokkyo University Hospital, Tochigi; Tsukuba University Hospital, Ibaraki; Tsukuba Medical Center, Ibaraki; Chiba University Hospital, Chiba; Funabashi Municipal Medical Center, Chiba; Kimitsu Chuo Hospital, Chiba; Chiba Rosai Hospital, Chiba; Tokai University Hospital, Kanagawa; Hamamatsu University Hospital, Shizuoka; Gifu University Hospital, Gifu; Chubu Rosai Hospital, Aichi; Mie University Hospital, Mie; Kanazawa Medical Collage, Ishikawa; Kobe Red Cross Hospital, Hyogo; Hiroshima University Hospital, Hiroshima; Yamaguchi University Hospital, Yamaguchi; and Nagasaki Rosai Hospital, Nagasaki.

Funding Statement

This trial is supported by Center for Clinical trials, Japan Medical Association, Japan.

Competing Interests

No authors have any competing interests to declare.

Contributorship Statement

MK, TF and MY contributed to planning and conduct of the present trial and to reporting the present protocol paper. HH, TS, YF, MH and ST contributed to conception and design of the present trial protocol and to reporting the present protocol paper. YI, JS, MK, SO, YM, TA, KW, TH, MO, HS, TM, IT, NK, MK. YO, TS, MY, MF, KY, DS, HT, DT, SI, HM, HU, FA, YS, IA, YT, MM, JS, YS, SI, HS, KT, YI, FN, MH, TO, FH, TF, KK, MW, HK, YM, YY, DT, TH, SK, GY, SO, TB, HA, KA, EK, HI, TS, AS, YI, TK, SO, NT, KN, NK, SK, HB, TO, HK, TY, IK, KY, TM, TM, IM, HK, TA, KH, TE, TS, MM, KF, SN, CI, TT, TK, HS, NN and MF contributed to conducting the present trial and to acquisition of data.

CONSORT 2010 checklist of information to include when reporting a randomised trial*

Section/Topic	ltem No	Checklist item	Reported on page No
Title and abstract			
	1a	Identification as a randomised trial in the title	1
	1b	Structured summary of trial design, methods, results, and conclusions (for specific guidance see CONSORT for abstracts)	3
Introduction			
Background and	2a	Scientific background and explanation of rationale	4-5
objectives	2b	Specific objectives or hypotheses	6
Methods			
Trial design	3a	Description of trial design (such as parallel, factorial) including allocation ratio	6
C C	3b	Important changes to methods after trial commencement (such as eligibility criteria), with reasons	N/A
Participants	4a	Eligibility criteria for participants	7
•	4b	Settings and locations where the data were collected	11
Interventions	5	The interventions for each group with sufficient details to allow replication, including how and when they were actually administered	6-7
Outcomes	6a	Completely defined pre-specified primary and secondary outcome measures, including how and when they were assessed	6-7
	6b	Any changes to trial outcomes after the trial commenced, with reasons	N/A
Sample size	7a	How sample size was determined	8
Randomisation:	7b	When applicable, explanation of any interim analyses and stopping guidelines	N/A
Sequence	8a	Method used to generate the random allocation sequence	6
generation	8b	Type of randomisation; details of any restriction (such as blocking and block size)	6
Allocation	9	Mechanism used to implement the random allocation sequence (such as sequentially numbered containers),	8
concealment mechanism		describing any steps taken to conceal the sequence until interventions were assigned	
Implementation	10	Who generated the random allocation sequence, who enrolled participants, and who assigned participants to interventions	6
Blinding	11a	If done, who was blinded after assignment to interventions (for example, participants, care providers, those	8

	446	assessing outcomes) and how	
	11b	If relevant, description of the similarity of interventions	<u>N/A</u>
Statistical methods		Statistical methods used to compare groups for primary and secondary outcomes	8-9
	12b	Methods for additional analyses, such as subgroup analyses and adjusted analyses	N/A
Results			
Participant flow (a diagram is strongly	, 13a	For each group, the numbers of participants who were randomly assigned, received intended treatment, and were analysed for the primary outcome	N/A
recommended)	, 13b	For each group, losses and exclusions after randomisation, together with reasons	N/A
Recruitment	14a	Dates defining the periods of recruitment and follow-up	N/A
Recruitment	14a 14b	Why the trial ended or was stopped	N/A
Baseline data	15	A table showing baseline demographic and clinical characteristics for each group	N/A
Numbers analysed		For each group, number of participants (denominator) included in each analysis and whether the analysis was	N/A
Numbers analysed	10	by original assigned groups	IN/A
Outcomes and	17a	For each primary and secondary outcome, results for each group, and the estimated effect size and its	N/A
estimation		precision (such as 95% confidence interval)	
	17b	For binary outcomes, presentation of both absolute and relative effect sizes is recommended	N/A
Ancillary analyses	18	Results of any other analyses performed, including subgroup analyses and adjusted analyses, distinguishing	N/A
		pre-specified from exploratory	
Harms	19	All important harms or unintended effects in each group (for specific guidance see CONSORT for harms)	N/A
Discussion			
Limitations	20	Trial limitations, addressing sources of potential bias, imprecision, and, if relevant, multiplicity of analyses	N/A
Generalisability	21	Generalisability (external validity, applicability) of the trial findings	N/A
Interpretation	22	Interpretation consistent with results, balancing benefits and harms, and considering other relevant evidence	N/A
Other information	1		
Registration	23	Registration number and name of trial registry	3
Protocol	24	Where the full trial protocol can be accessed, if available	3
	25	Sources of funding and other support (such as supply of drugs), role of funders	11

Abstract

Introduction: Granulocyte Colony Stimulating Factor (G-CSF) is generally used for neutropenia. Previous experimental studies revealed that G-CSF promoted neurological recovery after spinal cord injury (SCI). Next we moved to early phase of clinical trials. In a phase 1/2a trial, no adverse events were observed. Next, we conducted a non-randomized, non-blinded, comparative trial, which suggested the efficacy of G-CSF for promoting neurological recovery. Based on those results, we are now performing a phase 3 trial. Methods and Analysis: The objective of this study is to evaluate the efficacy of G-CSF for acute SCI. The study design is a prospective, multicenter, randomized, double-blinded, placebo-controlled comparative study. The current trial includes cervical SCI (severity of American Spinal Injury Association (ASIA) Impairment Scale B/C) within 48 hours after injury. Patients are randomly assigned to G-CSF and placebo groups. The G-CSF group is administered 400 μ g/m²/d×5d of G-CSF in normal saline via intravenous infusion for 5 consecutive days. The placebo group is similarly administered a placebo. Our primary endpoint is changes in ASIA motor scores from baseline to 3 months. Each group includes 44 patients (88 total patients). This trial is funded by the Center for Clinical Trials, Japan Medical Association.

Ethics and Dissemination: The study was approved by the Institutional Review Board of each institution and will be conducted according to the principles of the World Medical Association Declaration of Helsinki and in accordance with the Japanese Medical Research Involving Human Subjects Act and other guidelines, regulations and Acts. Results of the clinical study will be submitted to the head of the respective clinical study site as a report after conclusion of the clinical study by the sponsor-investigator. Even if the results are not favorable despite conducting the clinical study properly, the data will be published as a paper.

Strengths and Limitations of This Study

Strengths

- ✓ Novel drug therapy for acute spinal cord injury is much-needed.
- ✓ Randomized, placebo-controlled, double-blinded design can eliminate bias.

Limitations

- \checkmark Acute spinal cord injury patients are difficult to recruit to the trial.
- Patient's neurological status in acute phase is unstable, possibly resulting in dispersion of the patient's background.
- ✓ Concealment must be performed very strictly because G-CSF apparently increases

white blood cell count.

Introduction

Spinal cord injury (SCI) is a devastating injury by which the patient can suffer from long-lasting severe sequelae including palsy of extremities, sensory disturbance, bowel/bladder/sexual dysfunction, and neuropathic pain. Conceptually, SCI is divided into two chronological phases: a primary and a secondary phase. Primary injury is mechanical damage to spinal cord tissue itself caused by fracture and/or dislocation or compression. Secondary injury is triggered by the primary injury and is a biological reaction of the spinal cord, which includes ischemia, hemorrhage, excitotoxicity, hyperpermeability, and inflammation¹. Because secondary injury can be the main target of treatment, extensive laboratory and clinical investigation of neuroprotection is needed to manage secondary injury².

To date, the only approved neuroprotective therapy for SCI is massive methylprednisolone sodium succinate (MPSS) therapy based on the NASCIS 2 study³. However, recent reports revealed that MPSS shows only a modest effect for SCI. In addition, several reports have described adverse events induced by MPSS for SCI including infections (pneumonia, urinary tract infection) and gastrointestinal disorders (gastric ulcer, etc.)⁴. Therefore, the use of MPSS for SCI has become controversial⁵. Accordingly, a new therapeutic drug for SCI is desirable. BMJ Open: first published as 10.1136/bmjopen-2017-019083 on 5 May 2018. Granulocyte colony-stimulating factor (G-CSF, generic name: filgrastim) is a growth factor that affects the hematopoietic system, promoting differentiation, proliferation, and survival of granulocytes⁶. Clinically, in Japan, G-CSF is administered to patients with leukopenia, and to peripheral stem cell transplantation donors, G-CSF is administered to mobilize hematopoietic stem cells into the peripheral blood⁷. In the central nervous system, G-CSF has properties to mobilize the movement of bone marrow cells into the brain⁸ and spine, and in a stroke model, has shown neuroprotective properties⁹. In other countries, clinical studies of the effects of G-CSF in cerebral infarction have been reported¹⁰.

To prove the hypothesis that G-CSF has neuroprotective properties against SCI, G-CSF was administered to rat and mouse animal models of spinal cord injury, and hind limb

BMJ Open: first published as 10.1136/bmjopen-2017-019083 on 5 May 2018. Downloaded from http://bmjopen.bmj.com/ on March 3, 2023 by guest. Protected by copyright

function improved significantly after administration of G-CSF. Further investigations into the mechanism of action of G-CSF in SCI were conducted. Data obtained to date identify the following properties of G-CSF: [1] mobilization of bone marrow-derived stem cells causing their biointegration at the site of SCI¹¹, [2] direct inhibition of nerve cell death¹², [3] protection of the myelin sheath by inhibiting oligodendrocyte cell death¹³, [4] inhibition of inflammatory cytokine expression (TNF- α , IL-1 β)¹³, and [5] promotion of neovascularization¹⁴. These properties suggest that G-CSF has a neuroprotective effect in acute SCI.

Based on these properties, a phase 1/2a clinical study was conducted where the main objective was to confirm the safety and feasibility of G-CSF for treatment of patients with acute SCI¹⁵. This study was an open-label, dose-titrating study with no control group. As the initial step, 5 patients were given 5 μ g/kg/day of G-CSF for 5 consecutive days by i.v. infusion, and as the second step, 11 patients were given 10 μ g/kg/day of G-CSF for 5 consecutive days by i.v. infusion. No serious adverse events were noted, and the safety of G-CSF administration in patients with acute SCI was confirmed¹⁵.

As a next step, to validate the efficacy of G-CSF in neuroprotective treatment, a multicenter, prospective, nonrandomized, nonblinded, comparative control study (phase 2b clinical trial) was conducted¹⁶. Based on the results of the previous phase 1/2a clinical trial, the dosage and duration of treatment with G-CSF in this study was 10 μ g/kg/day for 5 consecutive days. Patients with acute cervical SCI (within 48 h of injury) were registered in the clinical trial and allocated to either the G-CSF group (G-CSF 10 μ g/kg/day × 5 days i.v. infusion) or control group (no G-CSF administration) at each treatment facility. A total of 19 patients in the G-CSF group and 26 patients in the control group were observed for 3 months or longer. American Spinal Injury Association (ASIA) motor score (motor: 0 to 100 points) was compared between the groups. ASIA motor scores were 26.1 ± 18.9 in the G-CSF group and 12.2 ± 14.7 in the control group showing a significant improvement of motor paralysis in the G-CSF group (p < 0.01). In addition, in cases that could be followed for 1 year or longer, a significant improvement of ASIA motor score was observed in the G-CSF group¹⁶.

BMJ Open

Based on results of these preclinical and early phase clinical trials, we are now conducting a phase 3 trial.

Specific Objective

The objective of this study is to evaluate the efficacy of G-CSF for improving motor paralysis in acute SCI.

Methods and Analysis

Design of the study

The study design of the current trial is a prospective, multicenter, randomized, double-blinded, placebo-controlled comparative study.

Study Procedures

The study outline is shown in Figure. Patients will be randomly assigned to G-CSF and placebo groups. A central registration system will be used for dynamic randomization into the investigational treatment group (G-CSF) and control group (placebo) based on age at registration (16–64 years of age, or 65–84 years of age) and severity of paralysis (AIS B or C) at 48 h after injury. With or without the surgical stabilization and/or decompression was not included in stratification. Initially, screened patients with severity AIS B/C will be tentatively enrolled. Initial screening of the patients include clinical laboratory test, imaging studies including X-ray, magnetic resonance imaging and computed tomography, and neurological/functional evaluations.

Neurological re-assessment will be performed 48±4 hours after SCI and the patients who will recover to severity AIS D will be excluded. The patients with severity AIS B/C at neurological re-assessment 48±4 hours after SCI will be enrolled and randomly allocated to either the investigational treatment group (G-CSF) or control group (placebo) in a 1 to 1 ratio. The subject registration center uses a program based on an appropriate computer algorithm to allocate patients into groups. The first dose of investigative drugs will be administered to the patients after re-assessment of neurological status and enrollment 48±4

hours after SCI.

The G-CSF group will be administered 400 μ g/m²/d × 5d of G-CSF in normal saline via intravenous infusion for 5 consecutive days. The placebo group will be similarly administered a placebo. The first dose of investigative drugs will be administered to the patients 48±4 hours after SCI. The dosing schedule will be once a day in every morning (9-10 AM) for consecutive 5 days even in case that the first dosing was performed at night because of restriction on practices. Investigational drugs including both G-CSF and placebo will be stored in refrigerator which will be kept between 1- 6□ and has temperature-logger in pharmacies in each participating institutes. The investigational drugs is packaged in ample with label only printed as serial numbers, ten ample is packed in one box with label only printed serial numbers. Web-based allocation system will show the serial number of investigational drug which must be used to respective patients to ensure blinding.

We decided dosage of drug based on our previous non-randomized early phase clinical studies. On phase 1/2a clinical study, of which study design was open-label, dose-titrating study with no control group, SCI patients who were administered 10 μ g/kg/day G-CSF for 5 days showed marked elevation of white blood cell number (reached nearly 50000/ μ l, of which WBC number might cause adverse effects of G-CSF) during G-CSF administration¹⁵. Therefore we decided to withdraw additional titration. In addition, next phase of clinical study, of which design was multicenter, prospective, nonrandomized, nonblinded, comparative control study, showed suggestive efficacy of G-CSF (10 μ g/kg/d for 5 days) for acute SCI¹⁶. Based on those results, we finally decided the dosage of G-CSF as 10 μ g/kg/d × 5d for 5 days. In the current clinical trial, the dosage of G-CSF is written as 400 μ g/m²/d (= 10 μ g/kg/d) according to the Japanese Pharmaceutical and Medical Device Agency (PMDA)'s instruction for consolidation with product labeling.

We decided to 48hours after SCI as the therapeutic time window because our previous multicenter, prospective, nonrandomized, nonblinded, comparative control study, which recruited SCI patients within 48 hours after injury, showed that there was no significant difference in neurological outcome between the patient administered G-CSF very early after the injury and 48 hours after injury¹⁶.

 $\mathbf{7}$

BMJ Open

Allocation will be concealed between blinded evaluators of efficacy/safety and those for laboratory data, as G-CSF markedly increases white blood cell counts that can reveal patient treatment.

Our primary endpoint is changes in ASIA motor scores (international standards for neurological classification of spinal cord injury (ISNSCI) suppl. Figure 1) from baseline to 3 months calculated as follows: 3-month ASIA motor score change = 3-month ASIA motor score – pretreatment ASIA motor score. To maintain consistency of neurological assessment among the each evaluators, attending lecture and e-learning (in website of International Spinal Cord Society: http://www.elearnsci.org/) of ASIA/ISNSCI scoring system is mandatory for every investigators participating to the present trial.

Secondary endpoints are as follows. [1] Change in ASIA motor scores at 6 months and 12 months after G-CSF administration compared with pretreatment. [2] Changes in sensory paralysis over time: change in ASIA sensory scores at 3 months, 6 months, and 12 months after G-CSF administration compared with pretreatment. [3] Severity of functional compromise because of paralysis: AIS before administration and at 3, 6, and 12 months after administration of G-CSF. [4] Percentage of responders: percentage of patients whose AIS improved by 1 grade or more at 3, 6, and 12 months after administration compared with before administration compared with before administration of G-CSF. [5] Neurological level of injury (NLI): percentage of patients whose NLI decreased by 1 grade of more at 3, 6, or 12 months after administration of G-CSF compared with pretreatment. [6] SCIM: change in SCIM scores at 3, 6, and 12 months after G-CSF administration compared with pretreatment [7] EQ-5D: measured EQ-5D efficacy scores at 3, 6, and 12 months after G-CSF.

To strengthen the analysis, more strict blindness of assessment by the evaluator for outcome measures is ideal. Therefore every prior score/measurement should be blinded and/or not the same person should assess every midpoint motor/sensory functional measurement. However, PMDA instructed us to assess one patients' functional evaluation by one evaluator for consistent assessment in respective patients. PMDA considers the consistency of assessment in respective patients is more important.

The precise explanation of abovementioned outcome measures is as followings (suppl.

BMJ Open: first published as 10.1136/bmjopen-2017-019083 on 5 May 2018. Downloaded from http://bmjopen.bmj.com/ on March 3, 2023 by guest. Protected by copyright

Figures). ASIA motor score is determined by examining a key muscle function within each of 10 myotomes on each side of the body on manual muscle testing (MMT) in the supine position. There is a range of score from 0 to 25 for each extremity, totaling 0 to 50 for the upper limbs and 0 to 50 for the lower limbs, resulting in total of ASIA motor score ranges from 0 to 100. This score can reflect the degree of motor impairment associated with the SCI (suppl. Figure 1). ASIA sensory scores is completed through the testing of a key point in each of the 28 dermatomes (from C2 to S4-5) on the right and left sides of the body that can be readily located in relation to bony anatomical landmarks. At each of these key points, two aspects of sensation are examined: light touch and pin prick. Appreciation of light touch and pin prick sensation at each of the key points is separately scored on a three-point scale, with comparison to the sensation on the patients' cheek as a normal frame of reference: 0 = absent, 1 = altered, 2 = normal or intact. As a result, ASIA sensory scores range from 0 to 112 (suppl. Figure 1). AIS designation is used in grading the degree of impairment: A = Complete. No sensory or motor function is preserved in the sacral segments S4-S5. B = Sensory incomplete. Sensory but not motor function is preserved below the neurological level. C = Motor incomplete. Motor function is preserved below the neurological level, and more than half of key muscle functions below the single neurological level of injury have a muscle grade less than 3 (Grades 0-2). D = Motor incomplete. Motor function is preserved below the neurological level, and at least half (half or more) of key muscle functions below the neurological level have a muscle grade >3. E = Normal. If sensation and motor function as tested are graded as normal in all segments, and the patient had prior deficits, then the AIS grade is E (suppl. Figure 1, footnote). NLI refers to the most caudal segment of the cord with intact sensation and antigravity muscle function strength, provided that there is normal (intact) sensory and motor function rostrally (suppl. Figure 1, footnote). SCIM is disability scale developed specifically for patients with spinal cord lesions in order to make the functional assessments of patients with paraplegia or tetraplegia more sensitive to changes. The SCIM includes the following areas of function: self-care (subscore (0-20), respiration and sphincter management (0-40) and mobility (0-40). Each area is scored according to its proportional weight in these patients'

general activity. The final score ranges from 0 to 100 (suppl. Figure 2-4). EQ-5D essentially consists of 2 pages (suppl. Figure 5, 6): the EQ-5D descriptive system and the EQ visual analogue scale (EQ VAS). The descriptive system comprises five dimensions: mobility, self-care, usual activities, pain/discomfort and anxiety/depression. Each dimension has 5 levels: no problems, slight problems, moderate problems, severe problems and extreme problems. The patient is asked to indicate his/her health state by ticking the box next to the most appropriate statement in each of the five dimension. This decision results in a 1-digit number that expresses the level selected for that dimension. The digits for the five dimensions can be combined into a 5-digit number that describes the patient's health state and can be converted to efficacy score with calibration scale (ranges -0.111 to 1.000). The EQ VAS records the patient's self-rated health on a vertical visual analogue scale, where the endpoints are labelled 'The best health you can imagine' and 'The worst health you can imagine'. The VAS can be used as a quantitative measure of health outcome that reflect the patient's own judgement.

Each group will include 44 patients (88 patients in total). Our protocol was approved by PMDA and this trial will be funded by the Center for Clinical Trials, Japan Medical Association.

BMJ Open: first published as 10.1136/bmjopen-2017-019083 on 5 May 2018. Downloaded from http://bmjopen.bmj.com/ on March 3, 2023 by guest. Protected by copyright

Inclusion

Inclusion criteria are as follows. [1] Patients with cervical SCI (severity of AIS B/C) within 48 h of injury. [2] Patients reassessed for neurological status at 48 h after injury, and those whose palsy is AIS B/C will be enrolled. [3] Patients with neurological level of injury between C4 and C7. [4] Patients with age of 16 to 85 years. [5] Patients who agree to participate in the current trial and from whom informed consent was obtained orally and in writing. [6] Patients who can be followed up for 12 months after SCI.

Exclusion

Exclusion criteria are as follows. [1] Patients with neurological recovery to AIS D at

BMJ Open: first published as 10.1136/bmjopen-2017-019083 on 5 May 2018. Downloaded from http://bmjopen.bmj.com/ on March 3, 2023 by guest. Protected by copyright

neurological reassessment 48 h after SCI, because only AIS B/C patients will be included to standardize the severity of paresis in order to stratify the patients at the initiation of drug administration. [2] Allergy to G-CSF. [3] Hematological malignancy, [4] within 6 months after invasive coronary intervention, [5] splenomegaly, or [6] pregnancy, [7] consciousness impairment, [8] neurological disorders that can affect neurological evaluation in the present trial, [9] fracture of extremities that can affect the neurological evaluation and [10] massive dose administration of MPSS. Exclusion criteria 2 - 6 are set for safety, criteria 1, 7 - 9 are set to maintain homogeneity of the patient population enrolled, criteria 7-9 are set for maintenance of accuracy of functional assessment, criteria 7 is set to obtain patients' own informed consent upon participation to the trial and criteria 10 is set to omit the possible interference of MPSS on outcome assessment.

Concealment

Patients will be administered drug or placebo and be evaluated in a double-blinded manner. An evaluator blinded to the treatment will take charge of patient evaluation including clinical findings and paresis, without laboratory data because G-CSF induces an apparent increase of white blood cell count that makes it easy to distinguish G-CSF and placebo treatment. Therefore, a non-blinded evaluator for laboratory data will be assigned to evaluate laboratory data alone. From a safety point-of view, the dose of G-CSF will be modulated according to excessive increase of white blood cell count. Therefore, a non-blinded evaluator will instruct the pharmacy to modulate the dose of G-CSF based on white blood cell count.

Sample Size Calculation

The target sample size for this randomized trial is 88. This number is based on the results of previous clinical trials¹⁶. The estimated group difference (\pm standard deviation) of change in ASIA motor scores from baseline to 3 months is 13.9 (\pm 21.9). A sample size of 44 patients in each group will provide 80% power to detect a difference of the change in ASIA motor scores between the G-CSF and the placebo treatments, using a mixed-effects

BMJ Open

Statistical analyses

The analyses of the primary and secondary end points will be performed as intention-to-treat analyses in a full analysis set, which includes all patients who: (1) took at least one course of treatment during the study; (2) do not present any serious violation of the study protocol; and (3) have data collected after commencement of treatment. For the baseline characteristics, summary statistics will comprise frequencies and proportions for categorical variables, and means and SDs for continuous variables. The patient characteristics will be compared using a chi-square test for categorical variables, and a *t* test or Wilcoxon rank sum test for continuous variables. Missing data including loss to follow-up and missing measurement will be supplemented with MMRM.

For the primary analysis, aimed at comparing treatment effects, a change in ASIA motor score from baseline to 3 months and its 95% confidence interval (CI) will be estimated using the MMRM. To test for significant association of the primary endpoint, a mixed effects model for repeated measures with an unstructured covariance matrix will be applied to adjust for age (<65 years or \geq 65 years) and AIS at 48 h after the injury (B or C).

For the secondary analysis, the change in ASIA motor score will be compared using a Student *t* test and the 95% CI will be estimated. The same method will be applied to change in sensory score, SCIM, and EQ-5D. A chi-squared test will be applied to the frequencies of the responder in AIS and of the improvement in NLI. The frequency of AIS will be summarized. The frequency of AEs will be compared using a Fisher exact test.

All comparisons are planned and all p values will be two sided. p < 0.05 will be considered significant. All statistical analyses will be performed using SAS software (version 9.4; SAS Institute, Cary, NC, USA). The statistical analysis plan will be developed by the principal investigator and the biostatistician before completion of patient recruitment and fixing of data.

Data Monitoring Committee

The data monitoring committee consists of three clinical trial specialists, including a biostatistician, who are independent from the current study. The committee will meet at least 2 times per year and all the data obtained by the current trial will be checked by the committee.

Adverse Events

As for safety evaluation, adverse events will be collected as follows. "Adverse events" refers to any untoward symptom or disease or signs of such (including clinical laboratory data abnormalities) in a clinical investigation subject after informed consent and does not necessarily have a causal relationship with the investigational product (G-CSF).

Increases in white blood counts will be considered an adverse event only when the count exceeds 50,000/µL from the perspective of a pharmacological effect of G-CSF, and any values below this will not be handled as an adverse event. Anaphylaxis and adult respiratory distress syndrome are the most representative G-CSF-related severe adverse events to be payed full attention.

All adverse events will code terminology used by the investigators according to the ICH International Medical Dictionary for Regulatory Activities Japanese version (MedDRA/J).

Ethics and Dissemination

Ethics

The study was approved by the Institutional Review Board (IRB) of each institutions involved to the present trial and will be conducted according to the principles of the World Medical Association (WMA) Declaration of Helsinki—Ethical Principles for Medical Research Involving Human Subjects with the amendments made in Seoul, South Korea, October 2008, with a Note of Clarification on Paragraph 29 added by the WMA General Assembly, Washington 2002; Note of Clarification on Paragraph 30 added by the WMA General Assembly, Tokyo 2004, and in accordance with the Japanese Medical Research

BMJ Open

Involving Human Subjects Act (WMO) and other guidelines, regulations and Acts.

Patient informed consent

The principal investigator will try to prepare the informed consent form and other explanatory materials in as simple language as possible in order to obtain informed consent from the patient and the patient's legal representative. In case that trial participants cannot sign the informed consent form due to upper extremity palsy caused by SCI, allograph by patients' representative will be allowed.

Public Disclosure and Publication Policy

Results of the clinical study will be submitted to the head of the respective clinical study site as a report after conclusion of the clinical study by the sponsor-investigator (includes study coordinating investigator). Even if the results are not favorable despite conducting the clinical study properly, the data will be published as a paper. Other sponsor-investigators (including the clinical study coordinating investigator), if they plan to publicize the data from this study in a specialized academic society conference or other external site, must first obtain permission from the other principal investigators and investigational product provider. In publicizing the results, the confidentiality of the subjects will be maintained and proofread in advance by the other sponsor-investigators (includes coordinating investigator) and investigational product provider.

Discussion

The current trial is a confirmative trial to elucidate the therapeutic efficacy of G-CSF for SCI. If the current trial can successfully show significant improvement of motor paralysis of SCI by G-CSF, we will move forward to drug approval application to the Ministry for Health and Labor, Japan. The entire protocol of the current trial was approved beforehand for the initiation of the current trial by the Japanese Pharmaceutical and Medical Device Agency (PMDA). The PMDA will also permit a drug approval application if significant efficacy of G-CSF for SCI is proven.

The current trial is an important milestone for SCI clinics and research to explore G-CSF for SCI.

Trial Status

The present trial is now on-going.

Trial Sites

Nineteen major hospitals in Japan constituting the G-SPIRIT study group as follows: Tohoku University Hospital, Miyagi; Niigata University, Niigata; Dokkyo University Hospital, Tochigi; Tsukuba University Hospital, Ibaraki; Tsukuba Medical Center, Ibaraki; Chiba University Hospital, Chiba; Funabashi Municipal Medical Center, Chiba; Kimitsu Chuo Hospital, Chiba; Chiba Rosai Hospital, Chiba; Tokai University Hospital, Kanagawa; Hamamatsu University Hospital, Shizuoka; Gifu University Hospital, Gifu; Chubu Rosai Hospital, Aichi; Mie University Hospital, Mie; Kanazawa Medical Collage, Ishikawa; Kobe Red Cross Hospital, Hyogo; Hiroshima University Hospital, Hiroshima; Yamaguchi University Hospital, Yamaguchi; and Nagasaki Rosai Hospital, Nagasaki.

Funding Statement

This trial is supported by Center for Clinical trials, Japan Medical Association, Japan.

Competing Interests

No authors have any competing interests to declare.

Contributorship Statement

MK, TF and MY contributed to planning and conduct of the present trial and to reporting the present protocol paper. HH, TS, YF, MH and ST contributed to conception and design of the present trial protocol and to reporting the present protocol paper. YI, JS, MK, SO, YM, TA, KW, TH, MO, HS, TM, IT, NK, MK. YO, TS, MY, MF, KY, DS, HT, DT, SI, HM, HU, FA, YS, IA, YT, MM, JS, YS, SI, HS, KT, YI, FN, MH, TO, FH, TF, KK, MW, HK, YM, YY, DT, TH, SK, GY, SO, TB, HA, KA, EK, HI, TS, AS, YI, TK, SO, NT, KN, NK, SK, HB, TO, HK, TY, IK, KY, TM, TM, IM, HK, TA, KH, TE, TS, MM, KF, SN, CI,

BMJ Open

TT, TK, HS, NN and MF contributed to conducting the present trial and to acquisition of data.

Section/Topic	ltem No	Checklist item	Reported on page No
Title and abstract			
	1a	Identification as a randomised trial in the title	1
	1b	Structured summary of trial design, methods, results, and conclusions (for specific guidance see CONSORT for abstracts)	3
ntroduction			
Background and	2a	Scientific background and explanation of rationale	4-5
objectives	2b	Specific objectives or hypotheses	6
Methods			
Frial design	3a	Description of trial design (such as parallel, factorial) including allocation ratio	6
	3b	Important changes to methods after trial commencement (such as eligibility criteria), with reasons	N/A
Participants	4a	Eligibility criteria for participants	7
	4b	Settings and locations where the data were collected	11
nterventions	5	The interventions for each group with sufficient details to allow replication, including how and when they were actually administered	6-7
Dutcomes	6a	Completely defined pre-specified primary and secondary outcome measures, including how and when they were assessed	6-7
	6b	Any changes to trial outcomes after the trial commenced, with reasons	N/A
Sample size	7a	How sample size was determined	8
	7b	When applicable, explanation of any interim analyses and stopping guidelines	N/A
Randomisation:			
Sequence	8a	Method used to generate the random allocation sequence	6
generation	8b	Type of randomisation; details of any restriction (such as blocking and block size)	6
Allocation concealment mechanism	9	Mechanism used to implement the random allocation sequence (such as sequentially numbered containers), describing any steps taken to conceal the sequence until interventions were assigned	8
Implementation	10	Who generated the random allocation sequence, who enrolled participants, and who assigned participants to interventions	6
Blinding	11a	If done, who was blinded after assignment to interventions (for example, participants, care providers, those	8

		assessing outcomes) and how	
	11b	If relevant, description of the similarity of interventions	N/A
Statistical methods	12a	Statistical methods used to compare groups for primary and secondary outcomes	8-9
	12b	Methods for additional analyses, such as subgroup analyses and adjusted analyses	N/A
Results			
Participant flow (a diagram is strongly	13a	For each group, the numbers of participants who were randomly assigned, received intended treatment, and were analysed for the primary outcome	N/A
recommended)	13b	For each group, losses and exclusions after randomisation, together with reasons	N/A
Recruitment	14a	Dates defining the periods of recruitment and follow-up	N/A
	14b	Why the trial ended or was stopped	N/A
Baseline data	15	A table showing baseline demographic and clinical characteristics for each group	N/A
Numbers analysed	16	For each group, number of participants (denominator) included in each analysis and whether the analysis was by original assigned groups	N/A
Outcomes and estimation	17a	For each primary and secondary outcome, results for each group, and the estimated effect size and its precision (such as 95% confidence interval)	N/A
	17b	For binary outcomes, presentation of both absolute and relative effect sizes is recommended	N/A
Ancillary analyses	18	Results of any other analyses performed, including subgroup analyses and adjusted analyses, distinguishing pre-specified from exploratory	N/A
Harms	19	All important harms or unintended effects in each group (for specific guidance see CONSORT for harms)	N/A
Discussion			
Limitations	20	Trial limitations, addressing sources of potential bias, imprecision, and, if relevant, multiplicity of analyses	N/A
Generalisability	21	Generalisability (external validity, applicability) of the trial findings	N/A
Interpretation	22	Interpretation consistent with results, balancing benefits and harms, and considering other relevant evidence	N/A
Other information			
Registration	23	Registration number and name of trial registry	3
Protocol	24	Where the full trial protocol can be accessed, if available	3
	25	Sources of funding and other support (such as supply of drugs), role of funders	11

Abstract

Introduction: Granulocyte Colony Stimulating Factor (G-CSF) is generally used for neutropenia. Previous experimental studies revealed that G-CSF promoted neurological recovery after spinal cord injury (SCI). Next we moved to early phase of clinical trials. In a phase 1/2a trial, no adverse events were observed. Next, we conducted a non-randomized, non-blinded, comparative trial, which suggested the efficacy of G-CSF for promoting neurological recovery. Based on those results, we are now performing a phase 3 trial. Methods and Analysis: The objective of this study is to evaluate the efficacy of G-CSF for acute SCI. The study design is a prospective, multicenter, randomized, double-blinded, placebo-controlled comparative study. The current trial includes cervical SCI (severity of American Spinal Injury Association (ASIA) Impairment Scale B/C) within 48 hours after injury. Patients are randomly assigned to G-CSF and placebo groups. The G-CSF group is administered 400 μ g/m²/d×5d of G-CSF in normal saline via intravenous infusion for 5 consecutive days. The placebo group is similarly administered a placebo. Our primary endpoint is changes in ASIA motor scores from baseline to 3 months. Each group includes 44 patients (88 total patients). This trial is funded by the Center for Clinical Trials, Japan Medical Association.

Ethics and Dissemination: The study was approved by the Institutional Review Board of each institution and will be conducted according to the principles of the World Medical Association Declaration of Helsinki and in accordance with the Japanese Medical Research Involving Human Subjects Act and other guidelines, regulations and Acts. Results of the clinical study will be submitted to the head of the respective clinical study site as a report after conclusion of the clinical study by the sponsor-investigator. Even if the results are not favorable despite conducting the clinical study properly, the data will be published as a paper.

Protocol version: Ver. 5.0 (2016/10/20)

Strengths and Limitations of This Study

Strengths

- ✓ Novel drug therapy for acute spinal cord injury is much-needed.
- ✓ Randomized, placebo-controlled, double-blinded design can eliminate bias.

Limitations

- \checkmark Acute spinal cord injury patients are difficult to recruit to the trial.
- Patient's neurological status in acute phase is unstable, possibly resulting in dispersion of the patient's background.

BMJ Open

Introduction

Spinal cord injury (SCI) is a devastating injury by which the patient can suffer from long-lasting severe sequelae including palsy of extremities, sensory disturbance, bowel/bladder/sexual dysfunction, and neuropathic pain. Conceptually, SCI is divided into two chronological phases: a primary and a secondary phase. Primary injury is mechanical damage to spinal cord tissue itself caused by fracture and/or dislocation or compression. Secondary injury is triggered by the primary injury and is a biological reaction of the spinal cord, which includes ischemia, hemorrhage, excitotoxicity, hyperpermeability, and inflammation¹. Because secondary injury can be the main target of treatment, extensive laboratory and clinical investigation of neuroprotection is needed to manage secondary injury².

To date, the only approved neuroprotective therapy for SCI is massive methylprednisolone sodium succinate (MPSS) therapy based on the NASCIS 2 study³. However, recent reports revealed that MPSS shows only a modest effect for SCI. In addition, several reports have described adverse events induced by MPSS for SCI including infections (pneumonia, urinary tract infection) and gastrointestinal disorders (gastric ulcer, etc.)⁴. Therefore, the use of MPSS for SCI has become controversial⁵. Accordingly, a new therapeutic drug for SCI is desirable.

Granulocyte colony-stimulating factor (G-CSF, generic name: filgrastim) is a growth factor that affects the hematopoietic system, promoting differentiation, proliferation, and survival of granulocytes⁶. Clinically, in Japan, G-CSF is administered to patients with leukopenia, and to peripheral stem cell transplantation donors, G-CSF is administered to mobilize hematopoietic stem cells into the peripheral blood⁷. In the central nervous system, G-CSF has properties to mobilize the movement of bone marrow cells into the brain⁸ and spine, and in a stroke model, has shown neuroprotective properties⁹. In other countries, clinical studies of the effects of G-CSF in cerebral infarction have been reported¹⁰.

To prove the hypothesis that G-CSF has neuroprotective properties against SCI, G-CSF

BMJ Open: first published as 10.1136/bmjopen-2017-019083 on 5 May 2018. Downloaded from http://bmjopen.bmj.com/ on March 3, 2023 by guest. Protected by copyright

was administered to rat and mouse animal models of spinal cord injury, and hind limb function improved significantly after administration of G-CSF. Further investigations into the mechanism of action of G-CSF in SCI were conducted. Data obtained to date identify the following properties of G-CSF: [1] mobilization of bone marrow-derived stem cells causing their biointegration at the site of SCI¹¹, [2] direct inhibition of nerve cell death¹², [3] protection of the myelin sheath by inhibiting oligodendrocyte cell death¹³, [4] inhibition of inflammatory cytokine expression (TNF- α , IL-1 β)¹³, and [5] promotion of neovascularization¹⁴. These properties suggest that G-CSF has a neuroprotective effect in acute SCI.

Based on these properties, a phase 1/2a clinical study was conducted where the main objective was to confirm the safety and feasibility of G-CSF for treatment of patients with acute SCI¹⁵. This study was an open-label, dose-titrating study with no control group. As the initial step, 5 patients were given 5 μ g/kg/day of G-CSF for 5 consecutive days by i.v. infusion, and as the second step, 11 patients were given 10 μ g/kg/day of G-CSF for 5 consecutive days by i.v. infusion. No serious adverse events were noted, and the safety of G-CSF administration in patients with acute SCI was confirmed¹⁵.

As a next step, to validate the efficacy of G-CSF in neuroprotective treatment, a multicenter, prospective, nonrandomized, nonblinded, comparative control study (phase 2b clinical trial) was conducted¹⁶. Based on the results of the previous phase 1/2a clinical trial, the dosage and duration of treatment with G-CSF in this study was 10 μ g/kg/day for 5 consecutive days. Patients with acute cervical SCI (within 48 h of injury) were registered in the clinical trial and allocated to either the G-CSF group (G-CSF 10 μ g/kg/day × 5 days i.v. infusion) or control group (no G-CSF administration) at each treatment facility. A total of 19 patients in the G-CSF group and 26 patients in the control group were observed for 3 months or longer. American Spinal Injury Association (ASIA) motor score (motor: 0 to 100 points) was compared between the groups. ASIA motor scores were 26.1 ± 18.9 in the G-CSF group and 12.2 ± 14.7 in the control group showing a significant improvement of motor paralysis in the G-CSF group (p < 0.01). In addition, in cases that could be followed for 1 year or longer, a significant improvement of ASIA motor score was observed in the

 $\mathbf{5}$

For peer review only - http://bmjopen.bmj.com/site/about/guidelines.xhtml

G-CSF group¹⁶.

Based on results of these preclinical and early phase clinical trials, we are now conducting a phase 3 trial.

Specific Objective

The objective of this study is to evaluate the efficacy of G-CSF for improving motor paralysis in acute SCI.

Methods and Analysis

Design of the study

The study design of the current trial is a prospective, multicenter, randomized, double-blinded, placebo-controlled comparative study.

Study Procedures

The study outline is shown in Figure. Patients will be randomly assigned to G-CSF and placebo groups. A central registration system will be used for dynamic randomization into the investigational treatment group (G-CSF) and control group (placebo) based on age at registration (16–64 years of age, or 65–84 years of age) and severity of paralysis (AIS B or C) at 48 h after injury. With or without the surgical stabilization and/or decompression was not included in stratification. Initially, screened patients with severity AIS B/C will be tentatively enrolled. Initial screening of the patients include clinical laboratory test, imaging studies including X-ray, magnetic resonance imaging and computed tomography, and neurological/functional evaluations.

Neurological re-assessment will be performed 48±4 hours after SCI and the patients who will recover to severity AIS D will be excluded. The patients with severity AIS B/C at neurological re-assessment 48±4 hours after SCI will be enrolled and randomly allocated to either the investigational treatment group (G-CSF) or control group (placebo) in a 1 to 1 ratio. The subject registration center uses a program based on an appropriate computer algorithm to allocate patients into groups. The first dose of investigative drugs will be

administered to the patients after re-assessment of neurological status and enrollment 48±4 hours after SCI.

The G-CSF group will be administered 400 μ g/m²/d × 5d of G-CSF in normal saline via intravenous infusion for 5 consecutive days. The placebo group will be similarly administered a placebo. The first dose of investigative drugs will be administered to the patients 48±4 hours after SCI. The dosing schedule will be once a day in every morning (9-10 AM) for consecutive 5 days even in case that the first dosing was performed at night because of restriction on practices. Investigational drugs including both G-CSF and placebo will be stored in refrigerator which will be kept between 1- 6 and has temperature-logger in pharmacies in each participating institutes. The investigational drugs is packaged in ample with label only printed as serial numbers, ten ample is packed in one box with label only printed serial numbers. Web-based allocation system will show the serial number of investigational drug which must be used to respective patients to ensure blinding.

We decided dosage of drug based on our previous non-randomized early phase clinical studies. On phase 1/2a clinical study, of which study design was open-label, dose-titrating study with no control group, SCI patients who were administered $10\mu g/kg/day$ G-CSF for 5 days showed marked elevation of white blood cell number (reached nearly 50000/µl, of which WBC number might cause adverse effects of G-CSF) during G-CSF administration¹⁵. Therefore we decided to withdraw additional titration. In addition, next phase of clinical study, of which design was multicenter, prospective, nonrandomized, nonblinded, comparative control study, showed suggestive efficacy of G-CSF (10 µg/kg/d for 5 days) for acute SCI¹⁶. Based on those results, we finally decided the dosage of G-CSF as 10 µg/kg/d × 5d for 5 days. In the current clinical trial, the dosage of G-CSF is written as 400 µg/m²/d (= 10 µg/kg/d) according to the Japanese Pharmaceutical and Medical Device Agency (PMDA)'s instruction for consolidation with product labeling.

We decided to 48hours after SCI as the therapeutic time window because our previous multicenter, prospective, nonrandomized, nonblinded, comparative control study, which recruited SCI patients within 48 hours after injury, showed that there was no significant difference in neurological outcome between the patient administered G-CSF very early

BMJ Open

after the injury and 48 hours after injury 16 .

Allocation will be concealed between blinded evaluators of efficacy/safety and those for laboratory data, as G-CSF markedly increases white blood cell counts that can reveal patient treatment.

Our primary endpoint is changes in ASIA motor scores (international standards for neurological classification of spinal cord injury (ISNSCI)¹⁷ suppl. Figure 1) from baseline to 3 months calculated as follows: 3-month ASIA motor score change = 3-month ASIA motor score – pretreatment ASIA motor score. To maintain consistency of neurological assessment among the each evaluators, attending lecture and e-learning (in website of International Spinal Cord Society: http://www.elearnsci.org/) of ASIA/ISNSCI scoring system is mandatory for every investigators participating to the present trial.

Secondary endpoints are as follows. [1] Change in ASIA motor scores¹⁷ at 6 months and 12 months after G-CSF administration compared with pretreatment. [2] Changes in sensory paralysis over time: change in ASIA sensory scores at 3 months, 6 months, and 12 months after G-CSF administration compared with pretreatment. [3] Severity of functional compromise because of paralysis: AIS before administration and at 3, 6, and 12 months after administration of G-CSF. [4] Percentage of responders: percentage of patients whose AIS improved by 1 grade or more at 3, 6, and 12 months after administration compared with before administration of G-CSF. [5] Neurological level of injury (NLI): percentage of patients whose NLI decreased by 1 grade of more at 3, 6, or 12 months after administration of G-CSF compared with pretreatment. [6] SCIM¹⁸: change in SCIM scores at 3, 6, and 12 months after G-CSF administration compared with pretreatment [7] EQ-5D¹⁹: measured EQ-5D efficacy scores at 3, 6, and 12 months after G-CSF.

To strengthen the analysis, more strict blindness of assessment by the evaluator for outcome measures is ideal. Therefore every prior score/measurement should be blinded and/or not the same person should assess every midpoint motor/sensory functional measurement. However, PMDA instructed us to assess one patients' functional evaluation by one evaluator for consistent assessment in respective patients. PMDA considers the consistency of assessment in respective patients is more important.

BMJ Open: first published as 10.1136/bmjopen-2017-019083 on 5 May 2018. Downloaded from http://bmjopen.bmj.com/ on March 3, 2023 by guest. Protected by copyright

The precise explanation of abovementioned outcome measures is as followings (suppl. Figures). ASIA motor score is determined by examining a function of 10 key muscles with manual muscle testing (MMT) in the supine position¹⁷. The score ranges from 0 to 25 for each extremity (MMT 0-5 in 5 muscles in each extremity), totaling 0 to 50 for the upper limbs and 0 to 50 for the lower limbs, resulting in total of ASIA motor score ranges from 0 to 100. ASIA motor score shows the degree of motor impairment induced by SCI (suppl. Figure 1)¹⁷. ASIA sensory scores is determined by sensory testing of a key point in each of the 28 dermatomes (from C2 to S4-5) on the each sides of the body. Two aspects of sensation are examined, light touch and pin prick, at all the key points. Light touch and pin prick sensation is separately scored on a three-point scale, 0 = absent, 1 = altered, 2 = normal or intact. As a result, ASIA sensory scores range from 0 to 112 (suppl. Figure 1) in light touch and pin prick respectively¹⁷. AIS is used for gross grading of impairment: A = Complete. No sensory or motor function is preserved in the sacral segments S4-S5. B = Sensory incomplete. Sensory but not motor function is preserved below the neurological level. C = Motor incomplete. Motor function is preserved below the neurological level, and more than half of key muscle functions below the single neurological level of injury have a muscle grade less than 3 (Grades 0-2). D = Motor incomplete. Motor function is preserved below the neurological level, and at least half (half or more) of key muscle functions below the neurological level have a muscle grade >3. $E = Normal^{17}$. If sensation and motor function as tested are graded as normal in all segments, and the patient had prior deficits, then the AIS grade is E (suppl. Figure 1, footnote)¹⁷. NLI refers to the most caudal segment of the cord with intact sensation and antigravity muscle function strength, provided that there is normal (intact) sensory and motor function rostrally (suppl. Figure 1, footnote)¹⁷. SCIM is disability scale developed specifically for patients with spinal cord lesions in order to make the functional assessments of patients with paraplegia or tetraplegia more sensitive to changes¹⁸. The SCIM includes the following areas of function: self-care (subscore (0-20), respiration and sphincter management (0-40) and mobility (0-40). Each area is scored according to its proportional weight in these patients' general activity¹⁸. The final score ranges from 0 to 100 (suppl.

Figure 2-4). EQ-5D essentially consists of 2 pages¹⁹ (suppl. Figure 5, 6): the EQ-5D descriptive system and the EQ visual analogue scale (EQ VAS). The descriptive system comprises five dimensions: mobility, self-care, usual activities, pain/discomfort and anxiety/depression. Each dimension has 5 levels: no problems, slight problems, moderate problems, severe problems and extreme problems. The patient is asked to indicate his/her health state by ticking the box next to the most appropriate statement in each of the five dimensions¹⁹. This decision results in a 1-digit number that expresses the level selected for that dimension. The digits for the five dimensions can be combined into a 5-digit number that describes the patient's health state and can be converted to efficacy score with calibration scale (ranges -0.111 to 1.000)¹⁹. The EQ VAS records the patient's self-rated health on a vertical visual analogue scale, where the endpoints are labelled 'The best health you can imagine' and 'The worst health you can imagine'. The VAS can be used as a quantitative measure of health outcome that reflect the patient's own judgement¹⁹.

Each group will include 44 patients (88 patients in total). Our protocol was approved by PMDA and this trial will be funded by the Center for Clinical Trials, Japan Medical Association.

BMJ Open: first published as 10.1136/bmjopen-2017-019083 on 5 May 2018. Downloaded from http://bmjopen.bmj.com/ on March 3, 2023 by guest. Protected by copyright

Inclusion

Inclusion criteria are as follows. [1] Patients with cervical SCI (severity of AIS B/C) within 48 h of injury. [2] Patients reassessed for neurological status at 48 h after injury, and those whose palsy is AIS B/C will be enrolled. [3] Patients with neurological level of injury between C4 and C7. [4] Patients with age of 16 to 85 years. [5] Patients who agree to participate in the current trial and from whom informed consent was obtained orally and in writing. [6] Patients who can be followed up for 12 months after SCI.

Exclusion

Exclusion criteria are as follows. [1] Patients with neurological recovery to AIS D at neurological reassessment 48 h after SCI, because only AIS B/C patients will be included to

standardize the severity of paresis in order to stratify the patients at the initiation of drug administration. [2] Allergy to G-CSF. [3] Hematological malignancy, [4] within 6 months after invasive coronary intervention, [5] splenomegaly, or [6] pregnancy, [7] consciousness impairment, [8] neurological disorders that can affect neurological evaluation in the present trial, [9] fracture of extremities that can affect the neurological evaluation and [10] massive dose administration of MPSS. Exclusion criteria 2 - 6 are set for safety, criteria 1, 7 - 9 are set to maintain homogeneity of the patient population enrolled, criteria 7-9 are set for maintenance of accuracy of functional assessment, criteria 7 is set to obtain patients' own informed consent upon participation to the trial and criteria 10 is set to omit the possible interference of MPSS on outcome assessment.

Concealment

Patients will be administered drug or placebo and be evaluated in a double-blinded manner. An evaluator blinded to the treatment will take charge of patient evaluation including clinical findings and paresis, without laboratory data because G-CSF induces an apparent increase of white blood cell count that makes it easy to distinguish G-CSF and placebo treatment. Therefore, a non-blinded evaluator for laboratory data will be assigned to evaluate laboratory data alone. From a safety point-of view, the dose of G-CSF will be modulated according to excessive increase of white blood cell count. Therefore, a non-blinded evaluator will instruct the pharmacy to modulate the dose of G-CSF based on white blood cell count.

Sample Size Calculation

The target sample size for this randomized trial is 88. This number is based on the results of previous clinical trials¹⁶. The estimated group difference (\pm standard deviation) of change in ASIA motor scores from baseline to 3 months is 13.9 (\pm 21.9). A sample size of 44 patients in each group will provide 80% power to detect a difference of the change in ASIA motor scores between the G-CSF and the placebo treatments, using a mixed-effects models for repeated measures (MMRM) at a two-sided 5% level of significance. A

BMJ Open

Statistical analyses

The analyses of the primary and secondary end points will be performed as intention-to-treat analyses in a full analysis set, which includes all patients who: (1) took at least one course of treatment during the study; (2) do not present any serious violation of the study protocol; and (3) have data collected after commencement of treatment. For the baseline characteristics, summary statistics will comprise frequencies and proportions for categorical variables, and means and SDs for continuous variables. The patient characteristics will be compared using a chi-square test for categorical variables, and a *t* test or Wilcoxon rank sum test for continuous variables. Missing data including loss to follow-up and missing measurement will be supplemented with MMRM.

For the primary analysis, aimed at comparing treatment effects, a change in ASIA motor score from baseline to 3 months and its 95% confidence interval (CI) will be estimated using the MMRM. To test for significant association of the primary endpoint, a mixed effects model for repeated measures with an unstructured covariance matrix will be applied to adjust for age (<65 years or \geq 65 years) and AIS at 48 h after the injury (B or C).

For the secondary analysis, the change in ASIA motor score will be compared using a Student *t* test and the 95% CI will be estimated. The same method will be applied to change in sensory score, SCIM, and EQ-5D. A chi-squared test will be applied to the frequencies of the responder in AIS and of the improvement in NLI. The frequency of AIS will be summarized. The frequency of AEs will be compared using a Fisher exact test.

All comparisons are planned and all p values will be two sided. p < 0.05 will be considered significant. All statistical analyses will be performed using SAS software (version 9.4; SAS Institute, Cary, NC, USA). The statistical analysis plan will be developed by the principal investigator and the biostatistician before completion of patient recruitment and fixing of data.

BMJ Open: first published as 10.1136/bmjopen-2017-019083 on 5 May 2018. Downloaded from http://bmjopen.bmj.com/ on March 3, 2023 by guest. Protected by copyright

Data Monitoring Committee

The data monitoring committee consists of three clinical trial specialists, including a biostatistician, who are independent from the current study. The committee will meet at least 2 times per year and all the data obtained by the current trial will be checked by the committee²⁰.

Adverse Events

As for safety evaluation, adverse events will be collected as follows. "Adverse events" refers to any untoward symptom or disease or signs of such (including clinical laboratory data abnormalities) in a clinical investigation subject after informed consent and does not necessarily have a causal relationship with the investigational product (G-CSF).

Increases in white blood counts will be considered an adverse event only when the count exceeds $50,000/\mu$ L from the perspective of a pharmacological effect of G-CSF, and any values below this will not be handled as an adverse event. Anaphylaxis and adult respiratory distress syndrome are the most representative G-CSF-related severe adverse events to be payed full attention.

All adverse events will code terminology used by the investigators according to the ICH International Medical Dictionary for Regulatory Activities Japanese version (MedDRA/J).

Ethics and Dissemination

Ethics

The study was approved by the Institutional Review Board (IRB) of each institutions involved to the present trial and will be conducted according to the principles of the World Medical Association (WMA) Declaration of Helsinki—Ethical Principles for Medical Research Involving Human Subjects with the amendments made in Seoul, South Korea, October 2008, with a Note of Clarification on Paragraph 29 added by the WMA General Assembly, Washington 2002; Note of Clarification on Paragraph 30 added by the WMA General Assembly, Tokyo 2004, and in accordance with the Japanese Medical Research Involving Human Subjects Act (WMO) and other guidelines, regulations and Acts.

The principal investigator will try to prepare the informed consent form and other explanatory materials in as simple language as possible in order to obtain informed consent from the patient and the patient's legal representative. In case that trial participants cannot sign the informed consent form due to upper extremity palsy caused by SCI, allograph by patients' representative will be allowed.

Public Disclosure and Publication Policy

Results of the clinical study will be submitted to the head of the respective clinical study site as a report after conclusion of the clinical study by the sponsor-investigator (includes study coordinating investigator). Even if the results are not favorable despite conducting the clinical study properly, the data will be published as a paper. Other sponsor-investigators (including the clinical study coordinating investigator), if they plan to publicize the data from this study in a specialized academic society conference or other external site, must first obtain permission from the other principal investigators and investigational product provider. In publicizing the results, the confidentiality of the subjects will be maintained and proofread in advance by the other sponsor-investigators (includes coordinating investigator) and investigational product provider.

Discussion

The current trial is a confirmative trial to elucidate the therapeutic efficacy of G-CSF for SCI. If the current trial can successfully show significant improvement of motor paralysis of SCI by G-CSF, we will move forward to drug approval application to the Ministry for Health and Labor, Japan. The entire protocol of the current trial was approved beforehand for the initiation of the current trial by the Japanese Pharmaceutical and Medical Device Agency (PMDA). The PMDA will also permit a drug approval application if significant efficacy of G-CSF for SCI is proven.

The current trial is an important milestone for SCI clinics and research to explore

G-CSF for SCI.

Trial Status

The present trial is now on-going.

Trial Sites

Nineteen major hospitals in Japan constituting the G-SPIRIT study group as follows: Tohoku University Hospital, Miyagi; Niigata University, Niigata; Dokkyo University Hospital, Tochigi; Tsukuba University Hospital, Ibaraki; Tsukuba Medical Center, Ibaraki; Chiba University Hospital, Chiba; Funabashi Municipal Medical Center, Chiba; Kimitsu Chuo Hospital, Chiba; Chiba Rosai Hospital, Chiba; Tokai University Hospital, Kanagawa; Hamamatsu University Hospital, Shizuoka; Gifu University Hospital, Gifu; Chubu Rosai Hospital, Aichi; Mie University Hospital, Mie; Kanazawa Medical Collage, Ishikawa; Kobe Red Cross Hospital, Hyogo; Hiroshima University Hospital, Hiroshima; Yamaguchi University Hospital, Yamaguchi; and Nagasaki Rosai Hospital, Nagasaki.

Funding Statement

This trial is supported by Center for Clinical trials, Japan Medical Association, Japan. (http://www.jmacct.med.or.jp/, tel: 81-3-5319-3781)

Competing Interests

No authors have any competing interests to declare.

Dookaround and	60	Description of research question and justification for undertaking the trial including summary of relevant	16
Background and rationale	6a	Description of research question and justification for undertaking the trial, including summary of relevant studies (published and unpublished) examining benefits and harms for each intervention	<u>4-6</u>
	6b	Explanation for choice of comparators	6
Objectives	7	Specific objectives or hypotheses	6
Trial design	8	Description of trial design including type of trial (eg, parallel group, crossover, factorial, single group), allocation ratio, and framework (eg, superiority, equivalence, noninferiority, exploratory)	<u>6-8</u>
Methods: Participa	nts, inte	erventions, and outcomes	
Study setting	9	Description of study settings (eg, community clinic, academic hospital) and list of countries where data will be collected. Reference to where list of study sites can be obtained	<u> 15</u>
Eligibility criteria	10	Inclusion and exclusion criteria for participants. If applicable, eligibility criteria for study centres and individuals who will perform the interventions (eg, surgeons, psychotherapists)	<u>11</u>
Interventions	11a	Interventions for each group with sufficient detail to allow replication, including how and when they will be administered	<u>6-8</u>
	11b	Criteria for discontinuing or modifying allocated interventions for a given trial participant (eg, drug dose change in response to harms, participant request, or improving/worsening disease)	<u>13</u>
	11c	Strategies to improve adherence to intervention protocols, and any procedures for monitoring adherence (eg, drug tablet return, laboratory tests)	_7_
	11d	Relevant concomitant care and interventions that are permitted or prohibited during the trial	<u>11</u>
Outcomes	12	Primary, secondary, and other outcomes, including the specific measurement variable (eg, systolic blood pressure), analysis metric (eg, change from baseline, final value, time to event), method of aggregation (eg, median, proportion), and time point for each outcome. Explanation of the clinical relevance of chosen efficacy and harm outcomes is strongly recommended	<u>8-10</u>
Participant timeline	13	Time schedule of enrolment, interventions (including any run-ins and washouts), assessments, and visits for participants. A schematic diagram is highly recommended (see Figure)	<u>Figure</u>

Page 3	31 o	f 30
--------	------	------

1				
2 3 4	Sample size	14	Estimated number of participants needed to achieve study objectives and how it was determined, including clinical and statistical assumptions supporting any sample size calculations	11-12
5 6 7	Recruitment	15	Strategies for achieving adequate participant enrolment to reach target sample size	<u> 15</u>
7 8 9	Methods: Assignme	ent of i	nterventions (for controlled trials)	
10	Allocation:			
11 12 13 14 15 16	Sequence generation	16a	Method of generating the allocation sequence (eg, computer-generated random numbers), and list of any factors for stratification. To reduce predictability of a random sequence, details of any planned restriction (eg, blocking) should be provided in a separate document that is unavailable to those who enrol participants or assign interventions	<u>6</u>
17 18 19 20	Allocation concealment mechanism	16b	Mechanism of implementing the allocation sequence (eg, central telephone; sequentially numbered, opaque, sealed envelopes), describing any steps to conceal the sequence until interventions are assigned	<u>6</u>
21 22 23	Implementation	16c	Who will generate the allocation sequence, who will enrol participants, and who will assign participants to interventions	<u> 6-7 </u>
24 25 26	Blinding (masking)	17a	Who will be blinded after assignment to interventions (eg, trial participants, care providers, outcome assessors, data analysts), and how	7, 11
27 28 29 30		17b	If blinded, circumstances under which unblinding is permissible, and procedure for revealing a participant's allocated intervention during the trial	<u>11</u>
31 32	Methods: Data coll	ection,	management, and analysis	
32 33 34 35 36 37	Data collection methods	18a	Plans for assessment and collection of outcome, baseline, and other trial data, including any related processes to promote data quality (eg, duplicate measurements, training of assessors) and a description of study instruments (eg, questionnaires, laboratory tests) along with their reliability and validity, if known. Reference to where data collection forms can be found, if not in the protocol	<u>8-10</u>
38 39 40 41 42 43		18b	Plans to promote participant retention and complete follow-up, including list of any outcome data to be collected for participants who discontinue or deviate from intervention protocols	<u>12-13</u>
44 45			For peer review only - http://bmjopen.bmj.com/site/about/guidelines.xhtml

2 3 4 5	Data management	19	Plans for data entry, coding, security, and storage, including any related processes to promote data quality (eg, double data entry; range checks for data values). Reference to where details of data management procedures can be found, if not in the protocol	<u>13</u>
6 7 8	Statistical methods	20a	Statistical methods for analysing primary and secondary outcomes. Reference to where other details of the statistical analysis plan can be found, if not in the protocol	<u>12-13</u>
9 10		20b	Methods for any additional analyses (eg, subgroup and adjusted analyses)	12-13
11 12 13 14		20c	Definition of analysis population relating to protocol non-adherence (eg, as randomised analysis), and any statistical methods to handle missing data (eg, multiple imputation)	<u>12-13</u>
15 16	Methods: Monitorin	g		
17 18 19 20 21	Data monitoring	21a	Composition of data monitoring committee (DMC); summary of its role and reporting structure; statement of whether it is independent from the sponsor and competing interests; and reference to where further details about its charter can be found, if not in the protocol. Alternatively, an explanation of why a DMC is not needed	<u>13</u>
22 23 24		21b	Description of any interim analyses and stopping guidelines, including who will have access to these interim results and make the final decision to terminate the trial	<u>N/A</u>
25 26 27	Harms	22	Plans for collecting, assessing, reporting, and managing solicited and spontaneously reported adverse events and other unintended effects of trial interventions or trial conduct	<u>13</u>
28 29 30	Auditing	23	Frequency and procedures for auditing trial conduct, if any, and whether the process will be independent from investigators and the sponsor	Not in he protocol
31 32	Ethics and dissemi	nation		
33 34 35 36	Research ethics approval	24	Plans for seeking research ethics committee/institutional review board (REC/IRB) approval	13-14
30 37 38 39 40 41	Protocol amendments	25	Plans for communicating important protocol modifications (eg, changes to eligibility criteria, outcomes, analyses) to relevant parties (eg, investigators, REC/IRBs, trial participants, trial registries, journals, regulators)	Patient consent form

BMJ Open

1 2 3	Consent or assent	26a	Who will obtain informed consent or assent from potential trial participants or authorised surrogates, and	<u>13</u>	
4			how (see Item 32)		
5 6 7		26b	Additional consent provisions for collection and use of participant data and biological specimens in ancillary studies, if applicable	<u>N/A</u>	
8 9 10	Confidentiality	27	How personal information about potential and enrolled participants will be collected, shared, and maintained in order to protect confidentiality before, during, and after the trial	_14	
11 12 13	Declaration of interests	28	Financial and other competing interests for principal investigators for the overall trial and each study site	15	
14 15 16	Access to data	29	Statement of who will have access to the final trial dataset, and disclosure of contractual agreements that limit such access for investigators	<u>_14</u>	
17 18 19	Ancillary and post- trial care	30	Provisions, if any, for ancillary and post-trial care, and for compensation to those who suffer harm from trial participation	Patient consent form	
20 21 22 23 24	Dissemination policy	31a	Plans for investigators and sponsor to communicate trial results to participants, healthcare professionals, the public, and other relevant groups (eg, via publication, reporting in results databases, or other data sharing arrangements), including any publication restrictions	_14	
25		31b	Authorship eligibility guidelines and any intended use of professional writers	14-15	
26 27 28		31c	Plans, if any, for granting public access to the full protocol, participant-level dataset, and statistical code	<u>N/A</u>	
29 30	Appendices				
31 32 33	Informed consent materials	32	Model consent form and other related documentation given to participants and authorised surrogates	Patient consent form	
34 35 36	Biological specimens	33	Plans for collection, laboratory evaluation, and storage of biological specimens for genetic or molecular analysis in the current trial and for future use in ancillary studies, if applicable	<u>N/A</u>	
37 38 39 40 41	*It is strongly recommended that this checklist be read in conjunction with the SPIRIT 2013 Explanation & Elaboration for important clarification on the items. Amendments to the protocol should be tracked and dated.
