BMJ Open is committed to open peer review. As part of this commitment we make the peer review history of every article we publish publicly available.

When an article is published we post the peer reviewers' comments and the authors' responses online. We also post the versions of the paper that were used during peer review. These are the versions that the peer review comments apply to.

The versions of the paper that follow are the versions that were submitted during the peer review process. They are not the versions of record or the final published versions. They should not be cited or distributed as the published version of this manuscript.

BMJ Open is an open access journal and the full, final, typeset and author-corrected version of record of the manuscript is available on our site with no access controls, subscription charges or pay-per-view fees (<http://bmjopen.bmj.com>).

If you have any questions on BMJ Open's open peer review process please email [info.bmjopen@bmj.com](mailto:info.bmjopen@bmj.com)

## ***Abstract***

*Objectives:* To (1) explore the clustering of community pharmacies in England; and (2) determine the relationship between community pharmacy clustering, urbanity and deprivation.

*Design:* An area level analysis spatial study.

*Setting:* England.

*Primary and secondary outcome measures:* Community pharmacy clustering determined as a community pharmacy located within 10 minutes walking distance to another community pharmacy.

*Participants:* Addresses and postcodes of each community pharmacy in England was used in the analysis. Each pharmacy postcode was assigned to a lower layer super output area (LSOA), which was then matched to urbanity (urban, town and fringe or village, hamlet and isolated dwellings) and deprivation decile (using the Index of Multiple Deprivation score).

## ***Results:***

Seventy five percent of community pharmacies in England were located in a 'cluster' (within 10 minutes walking distance of another pharmacy): 19% of community pharmacies were in a cluster of two, while 56% of community pharmacies were in clusters of three or more. There was a linear relationship between community pharmacy clustering and social deprivation – with clustering more prevalent in areas

1  
2  
3 of higher deprivation: for community pharmacies located in areas of lowest  
4 deprivation (decile 1), there was a significantly lower risk of clustering compared to  
5 community pharmacies located in areas of highest deprivation (RR 0.12 [95% CI 0.10,  
6 0.16]).  
7  
8  
9

10  
11  
12  
13 *Conclusions:*

14  
15 Clustering of community pharmacies in England is common, although there is a  
16 positive trend between community pharmacy clustering and social deprivation,  
17 whereby clustering is more significant in areas of high deprivation. As such,  
18 arrangements for future community pharmacy funding should not solely focus upon  
19 distance from one pharmacy to another, as means of determining funding allocation,  
20 as this could penalise community pharmacies in our most deprived communities, and  
21 potentially have a negative effect on other healthcare providers, such as GP and A&E  
22 services by increasing their workload.

### Strengths and limitations of this study

- This is the first study exploring community pharmacy clustering, and how this varies according to social deprivation, and urbanity
- We conceptualised a community pharmacy cluster using a 0.5 mile straight line, which is a limitation of the work
- We did not model what would happen for community pharmacy access if the clusters were removed due to community pharmacy closures

## Introduction

In recent years, community pharmacies have emerged as strategically important settings, which play a crucial role in delivering healthcare and public health services.[1] In the UK, for example, community pharmacies offer a range of tiered services: the first level of service, the essential service, includes dispensing medication, and providing medication-related advice; the second, the advanced service, allows pharmacists, amongst other things, to provide flu vaccinations and medicines use reviews; the third, the locally commissioned services, are used to address the needs of the local population, and can include smoking cessation, and minor illness schemes.[2] Importantly, through these patient-focused roles, community pharmacy services are able to reduce pressure from other healthcare providers, such as GPs and Accident and Emergency departments.[3, 4]

Indeed, with the average waiting times for a non-urgent GP appointment around 13 days, and the number of people waiting longer than 4 hours in Accident and Emergency departments increasing, it is clear UK healthcare services are under unprecedented strain.[5] Furthermore, it is known that people living in areas of higher socio-economic deprivation are more likely to need primary and secondary health services but that provision is in fact lower in these high-need neighbourhoods: the *inverse care law*. [6] The problem of timely access to healthcare services is therefore adversely affecting people in the most deprived communities – potentially further widening health inequalities and thereby putting even more pressure on healthcare services in the longer term. Previous work has shown that, in contrast to the *inverse care law* for GPs and hospital services, a *positive pharmacy care law* exists – whereby access to community pharmacies is highest in areas of highest

1  
2  
3 deprivation.[7] Community pharmacies are therefore able to reach people in the areas  
4 of greatest need thereby offering additional health care access in areas that are  
5 traditionally ‘under doctored’ – including rural areas.[8]  
6  
7

8  
9 Despite the significant – and perhaps underutilised – potential of community  
10 pharmacies, austerity has seen the implementation of UK government funding cuts to  
11 the English community pharmacy sector – with some estimates suggesting one in four  
12 community pharmacies could close as a result of the reduced funding envelope.[9] It  
13 has been argued that because community pharmacies cluster together, some can be cut  
14 without impacting on service provision. In a letter to the Pharmaceutical Services  
15 Negotiating Committee (PSNC - the body that represents NHS pharmacy contractors  
16 in England), the Department of Health state that “40% of pharmacies are in a cluster  
17 where there are three or more pharmacies within ten minutes’ walk” and that “in  
18 some parts of the country there are more pharmacies than are necessary to maintain  
19 good access”. [10] Despite these claims, and the potential impact on funding  
20 allocations and therefore service provision, there are no published studies that explore  
21 the clustering of community pharmacies in England, and how such clustering is linked  
22 to socio-economic deprivation, and urbanity. The research, therefore, aimed to: (1)  
23 explore the clustering of community pharmacies in England by ten minutes walking  
24 distance; and (2) determine the relationship between community pharmacy clustering,  
25 urbanity and deprivation.

## 48 **Methods**

### 49 *Design*

50  
51 This study used geographical information systems (GIS) to explore  
52 geographical access to community pharmacies, clustering and deprivation. For the  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 purposes of the study, a community pharmacy was defined as a premises registered  
4 with the General Pharmaceutical Council for the purposes of compounding,  
5 procurement, storage and distribution of medicines and appliances;[11] we excluded  
6 premises that were solely registered as Internet pharmacies in the analysis.  
7  
8  
9  
10

### 11 12 13 *Data and Variables*

14  
15  
16 Community pharmacy data were obtained from the Geo-healthcare access  
17 database.[12] This open access database contains data on the address and postcode of  
18 each community pharmacy premises in England (matched to their corresponding  
19 coordinates using the Office of National Statistics postcode directory,  
20 2014). Community pharmacy locations were mapped and their corresponding 2011  
21 lower layer super output areas (LSOA) were extracted. There are 32,844 LSOAs in  
22 England and these geographic areas comprise approximately 1 to 3000 people living  
23 in 400 to 1200 households, and were designed to improve the reporting of small area  
24 statistics. Urbanity is also a factor in access to healthcare services including  
25 community pharmacies so, using the Rural-Urban classification (2011) each  
26 community pharmacy LSOA was assigned to one of three categories: (1) urban, (2)  
27 town or fringe or village, and (3) hamlet and isolated dwellings.[8] These categories  
28 were aggregated from the original Rural-Urban classification which assigns areas to  
29 one of six rural or four urban settlement/context types. The 2015 Index of Multiple  
30 Deprivation (IMD) score was also matched to each community pharmacy's LSOA  
31 (from the Office of National Statistics). The IMD is an overall measure of multiple  
32 deprivation experienced by people living in an area, and comprises 37 separate  
33 indicators organized across seven domains of deprivation (income, employment,  
34

3 health and disability, education, skills and training, crime, barriers to housing and  
4 services and living environment) which are combined, using appropriate weights.[13]  
5  
6  
7

### 8 9 *Data Analysis*

10  
11 Locations of community pharmacies in England were mapped using ArcMap  
12 (version 10.3) and 0.5-mile (straight-line) buffers were placed around the site to  
13 represent a 10-minute walk, using an average walking speed of 3 miles (4 km) per  
14 hour.[14] The number of community pharmacies which were isolated, or clustered in  
15 groups of two, or three or more were then extracted for all locations. A cluster was  
16 defined if the buffer around a single community pharmacy contained two or more  
17 unique sites. The number of community pharmacies within each individual buffer  
18 was then calculated and summarised. In addition to examining data for all  
19 community pharmacies, further breakdown of clustering took place depending on  
20 whether or not the LSOA of the pharmacy was 'urban', 'town or fringe' or 'village,  
21 hamlet and isolated dwellings'. This process was repeated for all deprivation deciles  
22 based on the IMD 2015 for England, whereby the most deprived decile (decile 1)  
23 equated to the most deprived 10% of LSOAs, while the least deprived decile (decile  
24 10) represented the 10% least deprived LSOAs (Figure 1). The Relative Risk (RR) for  
25 community pharmacy clustering by deprivation were then calculated according to  
26 deprivation decile. For the deprivation analysis, a community pharmacy 'cluster' was  
27 considered as three or more community pharmacies within a 10-minute walking  
28 distance of each other.

## Results

Overall, our results show that, the percentage of community pharmacies within 10 minutes walking distance (0.5 mile) of one another is 75%: 19% of community pharmacies were in a cluster of two, while 56% of community pharmacies were in clusters of three or more. An example of community pharmacy clustering is shown visually in Figure 2.

### *Clustering of Community Pharmacies by Urban-Rural Classification*

For community pharmacies located in urban areas (n=10,438), there was no clustering for 19% of community pharmacies, 19 % were located in a cluster of two, while 62% were located in clusters of three or more. In town and fringe areas (n=1147), there was no clustering in 94% of community pharmacies, 5% were located in clusters of two, while 1% were located in clusters of three or more. In village areas (n=153), there was no clustering in 94% of community pharmacies, 4% were located in clusters of two, while 2% were located in clusters of three or more.

### *Clustering of Community Pharmacies by Index of Multiple Deprivation (IMD)*

When stratifying by IMD, there was, overall, a linear relationship between community pharmacy clustering and social deprivation – with clustering more prevalent in areas of higher deprivation (Figure 3); the highest percentage of community pharmacy clustering was 62%, observed in deprivation decile ten, while the lowest percentage of community pharmacy clustering was 8%, observed in deprivation decile one (Figure 4). Community pharmacies located in the most deprived areas were significantly more likely to exist as clusters: for community pharmacy clusters of three or more, there was a significantly higher risk of clustering

in deprivation decile ten, compared to all the other deciles. When comparing community pharmacies in decile one (least deprived) to community pharmacies in decile ten (most deprived), there was an 88% lower risk of clustering for community pharmacies in the least deprived areas (Table 1).

Deprivation Decile	No Clustering	Clustering of 2	Clustering of $\geq 3$
	RR (95% CI)	RR (95% CI)	RR (95% CI)
1	3.38 (3.06, 3.72)	1.20 (1.01, 1.43)	0.12 (0.10, 0.16)
2	3.08 (2.78, 3.39)	1.06 (0.89, 1.26)	0.27 (0.23, 0.31)
3	2.78 (3.51, 3.08)	1.28 (1.09, 1.49)	0.31 (0.27, 0.35)
4	2.52 (2.27, 2.80)	1.49 (1.29, 1.72)	0.34 (0.30, 0.38)
5	2.48 (2.23, 2.74)	1.40 (1.21, 1.62)	0.38 (0.34, 0.42)
6	2.41 (2.17, 2.67)	1.50 (1.32, 1.73)	0.37 (0.33, 0.42)
7	1.93 (1.73, 2.15)	1.53 (1.34, 1.75)	0.53 (0.49, 0.56)
8	1.83 (1.65, 2.04)	1.39 (1.22, 1.58)	0.60 (0.56, 0.65)
9	1.47 (1.31, 1.64)	1.40 (1.23, 1.59)	0.73 (0.68, 0.78)
10 (reference)	1	1	1

**Table 1:** Relative Risk (RR) of community pharmacy clustering according to deprivation decile (1 is the least deprived, while 10 is the most deprived).

### Discussion

The key findings of the study show that clustering of community pharmacies in England is common – with around 56% of all community pharmacies existing in a

1  
2  
3 cluster of three or more. There is also a positive trend between deprivation, and  
4  
5 community pharmacy clustering, whereby clustering is significantly more common in  
6  
7 areas of high deprivation. Clustering of community pharmacies was also more  
8  
9 common in urban areas, when compared to rural areas. This may well reflect both  
10  
11 health need and population size in the respective neighbourhoods.  
12

13  
14 This is the first study that has empirically explored whether community  
15  
16 pharmacies are clustered in England – and how such clustering varies according to  
17  
18 deprivation, and urbanity. Previous literature has shown that geographical proximity  
19  
20 of services can be an important consideration for healthcare utilization: for example,  
21  
22 Turnbull and colleagues showed that call rates to primary care centres decreased with  
23  
24 increasing distance. Furthermore, the same study also showed that higher call rates  
25  
26 were associated with more deprived areas.[15]  
27

28  
29 In terms of study limitations, whilst we believe our results are robust, and have  
30  
31 important policy implications for the way in which community pharmacies are  
32  
33 funded, we acknowledge there are several: firstly, we recognize that a 10-minute walk  
34  
35 (0.5 miles) from each community pharmacy was represented using a straight-line  
36  
37 distance from the central point of each community pharmacy's postcode to create a  
38  
39 buffer. This assumes people are able to walk in any direction from that postcode and  
40  
41 always in a straight line, while, in reality people are often constrained to pathways  
42  
43 that curve, or even be cut off by barriers (such as a lake, train tracks or busy roads).  
44  
45 We also acknowledge that we did not consider community pharmacy utilization in our  
46  
47 analysis; just because a community pharmacy is located in a particular area, does not  
48  
49 necessarily mean people from that area choose to use it. In addition, we did not  
50  
51 consider which types of service were being used from the community pharmacies; it  
52  
53 is possible that service utilization will change according to health need of the  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 population (*e.g.* people living in areas with a high prevalence of smoking might utilise  
4 more community pharmacy smoking cessation services). We also acknowledge that  
5 we did not explore how community pharmacy clustering varied according to  
6 population type; for example, it is possible that some community pharmacies serve  
7 different types of populations, such as black and minority ethnic groups, or older  
8 populations. It would be prudent, therefore, that future work establishes the types of  
9 people that utilize community pharmacies services, and how this varies according to  
10 urbanity, deprivation, and local health need.

11  
12  
13  
14  
15  
16  
17  
18  
19  
20 The policy implications of this work are clear: cutting the funding of  
21 community pharmacies by clustering will disproportionately affect community  
22 pharmacies located in the most deprived communities: potentially leading to an  
23 *inverse pharmacy care law*. Given that community pharmacies provide effective  
24 public health services,[16] this has the potential to further widen health inequalities –  
25 should community pharmacies in these areas close. Indeed, it would undermine the  
26 Department of Health’s responsibilities to reduce inequalities in access to NHS  
27 services. There have been recent reports of some large community pharmacy  
28 organisations taking the decision to close some of their community pharmacies as  
29 they have become “commercially unviable”, although it is not yet clear what areas  
30 will be affected.[17] We note that the Department of Health has recently introduced a  
31 Pharmacy Access Scheme (PhAS), whereby, according to specific criteria, certain  
32 community pharmacies will be protected from the reduction in funding.[18] Initially,  
33 community pharmacies would not qualify for the scheme if they were located within a  
34 one-mile radius of another community pharmacy, although we note that, in view of  
35 our preliminary work around community pharmacy clustering, the formula was  
36 modified to accommodate community pharmacies located in top 20 per cent of  
37  
38  
39

1  
2  
3 deprived areas in England within a 0.8 mile radius of another community  
4 pharmacy.[19] At present, however, it is not clear if community pharmacy clustering  
5 is driven by health need of the local area, or, as many community pharmacies are  
6 located in urban areas, they benefit from the increased footfall by being located in  
7 these areas. Future work should seek to address this important issue. While we are  
8 encouraged by the concept of the PhAS recognising community pharmacies in  
9 deprived areas, we believe that future models of funding should be based upon quality  
10 metrics around the provision of healthcare and public health services, rather focus on  
11 distance or clustering of pharmacies. The Department of Health has also recently  
12 introduced a quality payment scheme whereby extra payments will be paid to  
13 community pharmacies if certain quality criteria are met. We believe this is  
14 significant progress, and it is important that this concept continue which will remove  
15 focus on the number of services a community pharmacy undertakes, to that of the  
16 quality of the service a community pharmacy undertakes. This will help direct  
17 funding to community pharmacies that are engaged in delivering the higher levels of  
18 service.

59  
60  
In terms of the impact on the wider healthcare community, previous work  
shows that if community pharmacy services were not present, people would use  
alternate – and more costly – branches of the NHS, such as GP and Accident and  
Emergency services.[3] It is also evident that people living in more deprived areas  
experience higher morbidity much earlier in life, compared to people living in affluent  
areas – as represented by lower healthy life expectancy is for example.[20] A study  
analyzing one million GP consultations in London showed that someone aged 50  
years living in the most deprived quintile of English neighbourhoods consults with  
their GP at the same rate as someone aged 70 years in the most affluent quintile of

1  
2  
3 neighbourhoods.[21] So, community pharmacy closures – particularly in deprived  
4 areas – are likely to increase the workload of general practice. Community  
5 pharmacies are able to reach people that other services cannot. For example, a study  
6 has shown that owing to their wider accessibility (e.g. proximity; opening times, no  
7 appointment required), many people prefer to obtain healthcare from a community  
8 pharmacy setting [22] and a qualitative study revealed some people were more likely  
9 to use a community pharmacy for healthcare advice owing to their trusting  
10 relationship they develop with the pharmacist.[23]

### 21 22 *Conclusion*

23  
24 Just over half of community pharmacies in England are located in clusters of  
25 three or more by ten minutes walking distance. There is also a positive trend between  
26 community pharmacy clustering and social deprivation, whereby clustering is  
27 significantly more common in areas of high deprivation. As such, arrangements for  
28 future community pharmacy funding should not solely focus upon distance from one  
29 pharmacy to another, as means of determining funding allocation, as this could  
30 penalise community pharmacies in our most deprived communities, and potentially  
31 have a negative effect on other healthcare providers, such as GP and A&E services by  
32 increasing their workload. Future funding models of community pharmacy should  
33 consider quality of healthcare and public health services provided, as well as health  
34 need of the local area.

## ***Abstract***

*Objectives:* To (1) explore the clustering of community pharmacies in England; and (2) determine the relationship between community pharmacy clustering, urbanity and deprivation.

*Design:* An area level analysis spatial study.

*Setting:* England.

*Primary and secondary outcome measures:* Community pharmacy clustering determined as a community pharmacy located within 10 minutes walking distance to another community pharmacy.

*Participants:* Addresses and postcodes of each community pharmacy in England was used in the analysis. Each pharmacy postcode was assigned to a lower layer super output area (LSOA), which was then matched to urbanity (urban, town and fringe or village, hamlet and isolated dwellings) and deprivation decile (using the Index of Multiple Deprivation score).

## *Results:*

Seventy five percent of community pharmacies in England were located in a 'cluster' (within 10 minutes walking distance of another pharmacy): 19% of community pharmacies were in a cluster of two, while 56% of community pharmacies were in clusters of three or more. There was a linear relationship between community

1  
2  
3 pharmacy clustering and social deprivation – with clustering more prevalent in areas  
4 of higher deprivation: for community pharmacies located in areas of lowest  
5 deprivation (decile 1), there was a significantly lower risk of clustering compared to  
6 community pharmacies located in areas of highest deprivation (RR 0.12 [95% CI 0.10,  
7 0.16]).  
8  
9  
10  
11  
12

13  
14  
15 *Conclusions:*

16 Clustering of community pharmacies in England is common, although there is a  
17 positive trend between community pharmacy clustering and social deprivation,  
18 whereby clustering is more significant in areas of high deprivation. As such,  
19 arrangements for future community pharmacy funding should not solely focus upon  
20 distance from one pharmacy to another, as means of determining funding allocation,  
21 as this could penalise community pharmacies in our most deprived communities, and  
22 potentially have a negative effect on other healthcare providers, such as GP and A&E  
23 services by increasing their workload.

### Strengths and limitations of this study

- This is the first study exploring community pharmacy clustering, and how this varies according to social deprivation, and urbanity
- We conceptualised a community pharmacy cluster using a 0.5 mile straight line, which is a limitation of the work
- We did not model what would happen for community pharmacy access if the clusters were removed due to community pharmacy closures

## Introduction

In recent years, community pharmacies have emerged as strategically important settings, which play a crucial role in delivering healthcare and public health services.[1] In the UK, for example, community pharmacies offer a range of tiered services: the first level of service, the essential service, includes dispensing medication, and providing medication-related advice; the second, the advanced service, allows pharmacists, amongst other things, to provide flu vaccinations and medicines use reviews; the third, the locally commissioned services, are used to address the needs of the local population, and can include smoking cessation, and minor illness schemes.[2] Importantly, through these patient-focused roles, community pharmacy services are able to manage people with minor illnesses and some long-term conditions. This is advantageous, people with minor illness can be directed away from other healthcare providers, such as GPs and Accident and Emergency departments.[3, 4] This approach therefore has the potential to free up valuable healthcare resource, which allows other primary and secondary care services to manage people with more serious conditions where community pharmacy involvement would not be appropriate.

Indeed, with the average waiting times for a non-urgent GP appointment around 13 days, and the number of people waiting longer than 4 hours in Accident and Emergency departments increasing, it is clear UK healthcare services are under unprecedented strain.[5] Furthermore, it is known that people living in areas of higher socio-economic deprivation are more likely to need primary and secondary health services, but that provision is in fact lower in these high-need neighbourhoods: the *inverse care law*. [6] The problem of timely access to healthcare services is therefore

1  
2  
3 adversely affecting people in the most deprived communities – potentially further  
4 widening health inequalities and thereby putting even more pressure on healthcare  
5 services in the longer term. Previous work has shown that, in contrast to the *inverse*  
6 *care law* for GPs and hospital services, a *positive pharmacy care law* exists –  
7 whereby people living in areas of highest deprivation have better access to  
8 community pharmacies.[7] It is also known that the urbanity is an area is in important  
9 consideration for healthcare access, with people from urban areas living in greater  
10 proximity to GP services, when compared to people living in rural areas.[8]  
11 Community pharmacies therefore have the potential to reach people in the areas of  
12 greatest need thereby offering additional health care access in areas that are  
13 traditionally ‘under doctored’ – including rural areas.[8]

Despite the significant – and perhaps underutilised – potential of community  
pharmacies, austerity has seen the implementation of UK government funding cuts to  
the English community pharmacy sector – with some estimates suggesting one in four  
community pharmacies could close as a result of the reduced funding envelope.[9] It  
has been argued that because community pharmacies cluster together, some can be cut  
without impacting on service provision. In a letter to the Pharmaceutical Services  
Negotiating Committee (PSNC - the body that represents NHS pharmacy contractors  
in England), the Department of Health state that “40% of pharmacies are in a cluster  
where there are three or more pharmacies within ten minutes’ walk” and that “in  
some parts of the country there are more pharmacies than are necessary to maintain  
good access”. [10] Despite these claims, and the potential impact on funding  
allocations and therefore service provision, there are no published studies that explore  
the clustering of community pharmacies in England, and how such clustering is linked  
to socio-economic deprivation, and urbanity. The research, therefore, aimed to: (1)

1  
2  
3 explore the clustering of community pharmacies in England by ten minutes walking  
4 distance; and (2) determine the relationship between community pharmacy clustering,  
5 urbanity and deprivation.  
6

## 10 11 **Methods**

### 12 *Design*

13  
14  
15 This study used geographical information systems (GIS) to explore  
16 community pharmacy clustering according to urbanity and deprivation. For the  
17 purposes of the study, a community pharmacy was defined as a premises registered  
18 with the General Pharmaceutical Council for the purposes of compounding,  
19 procurement, storage and distribution of medicines and appliances;[11] we excluded  
20 premises that were solely registered as Internet pharmacies in the analysis.  
21  
22

24  
25  
26  
27  
28  
29  
30

### 31 *Data and Variables*

32  
33 Community pharmacy data were obtained from the Geo-healthcare access  
34 database.[12] This open access database contains data on the address and postcode of  
35 each community pharmacy premises in England (matched to their corresponding  
36 coordinates using the Office of National Statistics postcode directory, 2014); the last  
37 update of the dataset was in 2016. Community pharmacy locations were mapped and  
38 their corresponding 2011 lower layer super output areas (LSOA) were extracted.  
39 There are 32,844 LSOAs in England and these geographic areas comprise  
40 approximately 1 to 3000 people living in 400 to 1200 households, and were designed  
41 to improve the reporting of small area statistics. Urbanity is also a factor in access to  
42 healthcare services including community pharmacies so, using the Rural-Urban  
43 classification (2011) each community pharmacy LSOA was assigned to one of three  
44  
45  
46

2  
3 categories: (1) urban, (2) town or fringe or village, and (3) hamlet and isolated  
4 dwellings. These categories were aggregated from the original Rural-Urban  
5 classification which assigns areas to one of six rural or four urban settlement/context  
6 types. The 2015 Index of Multiple Deprivation (IMD) score was also matched to  
7 each community pharmacy's LSOA (from the Office of National Statistics). The  
8 IMD is an overall measure of multiple deprivation experienced by people living in an  
9 area, and comprises 37 separate indicators organized across seven domains of  
10 deprivation (income, employment, health and disability, education, skills and training,  
11 crime, barriers to housing and services and living environment) which are combined,  
12 using appropriate weights.[13]

24  
25

### 26 *Data Analysis*

27  
28  
29 Locations of community pharmacies in England were mapped using ArcMap  
30 (version 10.3) and 0.5-mile (straight-line) buffers were placed around the site to  
31 represent a 10-minute walk, using an average walking speed of 3 miles (4 km) per  
32 hour.[14] The number of community pharmacies which were isolated, or clustered in  
33 groups of two, or three or more were then extracted for all locations. A cluster was  
34 defined if the buffer around a single community pharmacy contained two or more  
35 unique sites. The number of community pharmacies within each individual buffer  
36 was then calculated and summarised. In addition to examining data for all  
37 community pharmacies, further breakdown of clustering took place depending on  
38 whether or not the LSOA of the pharmacy was 'urban', 'town or fringe' or 'village,  
39 hamlet and isolated dwellings'. This process was repeated for all deprivation deciles  
40 based on the IMD 2015 for England, whereby the most deprived decile (decile 1)  
41 equated to the most deprived 10% of LSOAs, while the least deprived decile (decile  
42  
43  
44  
45  
46

2  
3 10) represented the 10% least deprived LSOAs (Figure 1). The Relative Risk (RR) for  
4 community pharmacy clustering by deprivation were then calculated according to  
5 deprivation decile. For the deprivation analysis, a community pharmacy 'cluster' was  
6 considered as three or more community pharmacies within a 10-minute walking  
7 distance of each other.  
8  
9  
10  
11  
12

### 13 14 15 16 *Patient and Public Involvement*

17 As this study involved secondary data analysis from the Geo-healthcare access  
18 database, patients or the public were not involved in the design, or delivery of this  
19 research.  
20  
21  
22  
23  
24  
25

### 26 *Ethical approval*

27 Ethical approval of this work was not required, as the study used non-patient  
28 identifiable secondary data; patients were not actively involved in this research.  
29  
30  
31  
32  
33  
34

### 35 *Results*

36 Overall, our results show that, the percentage of community pharmacies  
37 within 10 minutes walking distance (0.5 mile) of one another is 75%: 19% of  
38 community pharmacies were in a cluster of two, while 56% of community pharmacies  
39 were in clusters of three or more. An example of community pharmacy clustering is  
40 shown visually in Figure 2.  
41  
42  
43  
44  
45  
46  
47  
48  
49

### 50 *Clustering of Community Pharmacies by Urban-Rural Classification*

51 For community pharmacies located in urban areas (n=10,438), there was no  
52 clustering for 19% of community pharmacies, 19 % were located in a cluster of two,  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 while 62% were located in clusters of three or more. In town and fringe areas  
4 (n=1147), there was no clustering in 94% of community pharmacies, 5% were located  
5  
6 in clusters of two, while 1% were located in clusters of three or more. In village areas  
7  
8 (n=153), there was no clustering in 94% of community pharmacies, 4% were located  
9  
10 in clusters of two, while 2% were located in clusters of three or more.  
11  
12  
13

### 14 15 16 *Clustering of Community Pharmacies by Index of Multiple Deprivation (IMD)* 17

18 When stratifying by IMD, there was, overall, a linear relationship between  
19  
20 community pharmacy clustering and social deprivation – with clustering more  
21  
22 prevalent in areas of higher deprivation (Figure 3); the highest percentage of  
23  
24 community pharmacy clustering was 62%, observed in deprivation decile ten, while  
25  
26 the lowest percentage of community pharmacy clustering was 8%, observed in  
27  
28 deprivation decile one (Figure 4). Community pharmacies located in the most  
29  
30 deprived areas were significantly more likely to exist as clusters: for community  
31  
32 pharmacy clusters of three or more, there was a significantly higher risk of clustering  
33  
34 in deprivation decile ten, compared to all the other deciles. When comparing  
35  
36 community pharmacies in decile one (least deprived) to community pharmacies in  
37  
38 decile ten (most deprived), there was an 88% lower risk of clustering for community  
39  
40 pharmacies in the least deprived areas (Table 1).

**Table 1:** Relative Risk (RR) of community pharmacy clustering according to deprivation decile (1 is the least deprived, while 10 is the most deprived).

### **Discussion**

The key findings of the study show that clustering of community pharmacies in England is common – with around 56% of all community pharmacies existing in a cluster of three or more. There is also a positive trend between deprivation, and community pharmacy clustering, whereby clustering is significantly more common in areas of high deprivation. Clustering of community pharmacies was also more

1  
2  
3 common in urban areas, when compared to rural areas. This may well reflect both  
4  
5 health need and population size in the respective neighbourhoods.  
6

7  
8 This is the first study that has empirically explored whether community  
9  
10 pharmacies are clustered in England – and how such clustering varies according to  
11  
12 deprivation, and urbanity. Previous literature has shown that geographical proximity  
13  
14 of services can be an important consideration for healthcare utilization: for example,  
15  
16 Turnbull and colleagues showed that call rates to primary care centres decreased with  
17  
18 increasing distance. Furthermore, the same study also showed that higher call rates  
19  
20 were associated with more deprived areas.[15] Furthermore, Lin and colleagues  
21  
22 examined travel distance to hospital and the associated effect on hospitalisations in  
23  
24 Canada, and showed that admission rates were inversely proportional to hospital  
25  
26 distance.[16] It has also been shown in the literature that proximity to healthcare  
27  
28 services is not only an important consideration for healthcare utilization, but is an  
29  
30 important factor for health outcome. For example, a study by Okwaraji and colleagues  
31  
32 showed that, in a remote area of rural Ethiopia, the distance to the nearest health  
33  
34 centre had a significant effect on child mortality – with children living greater than  
35  
36 1.5 hours walk from the health centre having a two to three greater risk of death  
37  
38 compared to children who live within 1.5 hours walk.[17] Clearly the context of this  
39  
40 work is different to healthcare settings in England, so limited comparisons can be  
41  
42 drawn. However, given the well-established relationship between health and place, it  
43  
44 would be prudent for future research to explore how community pharmacy  
45  
46 distribution is associated with health of a particular area. The literature has also  
47  
48 shown that healthcare access from a geographical perspective tends to be lower  
49  
50 amongst rural communities when compared to more urban communities. For  
51  
52 example, Lovatt and colleagues, who explore GP accessibility by car travel and public  
53  
54  
55  
56  
57  
58  
59

1  
2  
3 transport, showed examples of rural areas in East Anglia (typically with low levels of  
4 personal mobility and high health need) where there was no daytime bus services or  
5 no community transport, which allowed travel/access to a GP.[18] These challenges  
6 have been summarised by Baird and Wright, who coined the term ‘rural health  
7 deprivation’, and argue that, to improve the health of the nation, more needs to be  
8 done to develop care pathways for rural communities.[19] Although we have not  
9 measured accessibility of community pharmacy by population, our findings that  
10 community pharmacy clustering is lower in rural areas lend support to the hypothesis  
11 that accessibility to healthcare is lower amongst rural communities.  
12

19  
20  
21

22 In terms of study limitations, whilst we believe our results are robust, and have  
23 important policy implications for the way in which community pharmacies are  
24 funded, we acknowledge there are several: firstly, we recognize that a 10-minute walk  
25 (0.5 miles) from each community pharmacy was represented using a straight-line  
26 distance from the central point of each community pharmacy's postcode to create a  
27 buffer. This assumes people are able to walk in any direction from that postcode and  
28 always in a straight line, while, in reality people are often constrained to pathways  
29 that curve, or even be cut off by barriers (such as a lake, train tracks or busy roads).  
30 We also acknowledge that we did not consider community pharmacy utilization in our  
31 analysis; just because a community pharmacy is located in a particular area, does not  
32 necessarily mean people from that area choose to use it. In addition, we did not  
33 consider which types of service were being used from the community pharmacies; it  
34 is possible that service utilization will change according to health need of the  
35 population (*e.g.* people living in areas with a high prevalence of smoking might utilise  
36 more community pharmacy smoking cessation services). We also acknowledge that  
37 we did not explore how community pharmacy clustering varied according to  
38  
39  
40  
41

57  
58  
59  
60

1  
2  
3 population type; for example, it is possible that some community pharmacies serve  
4 different types of populations, such as black and minority ethnic groups, or older  
5 populations. It would be prudent, therefore, that future work establishes the types of  
6 people that utilize community pharmacies services, and how this varies according to  
7 urbanity, deprivation, and local health need.  
8  
9

10  
11  
12  
13 The policy implications of this work are clear: cutting the funding of  
14 community pharmacies by clustering will disproportionately affect community  
15 pharmacies located in the most deprived communities: potentially leading to an  
16 *inverse pharmacy care law*. Given that community pharmacies provide effective  
17 public health services,[20] this has the potential to further widen health inequalities –  
18 should community pharmacies in these areas close. Indeed, it would undermine the  
19 Department of Health’s responsibilities to reduce inequalities in access to NHS  
20 services. There have been recent reports of some large community pharmacy  
21 organisations taking the decision to close some of their community pharmacies as  
22 they have become “commercially unviable”, although it is not yet clear what areas  
23 will be affected.[21] We note that the Department of Health has recently introduced a  
24 Pharmacy Access Scheme (PhAS), whereby, according to specific criteria, certain  
25 community pharmacies will be protected from the reduction in funding.[22] Initially,  
26 community pharmacies would not qualify for the scheme if they were located within a  
27 one-mile radius of another community pharmacy, although we note that, in view of  
28 our preliminary work around community pharmacy clustering, the formula was  
29 modified to accommodate community pharmacies located in top 20 per cent of  
30 deprived areas in England within a 0.8 mile radius of another community  
31 pharmacy.[23] At present, however, it is not clear if community pharmacy clustering  
32 is driven by health need of the local area, or, as many community pharmacies are  
33  
34

1  
2  
3 located in urban areas, they benefit from the increased footfall by being located in  
4 these areas. Future work should seek to address this important issue. While we are  
5 encouraged by the concept of the PhAS recognising community pharmacies in  
6 deprived areas, we believe that future models of funding should be based upon quality  
7 metrics around the provision of healthcare and public health services, rather focus on  
8 distance or clustering of pharmacies. The Department of Health has also recently  
9 introduced a quality payment scheme whereby extra payments will be paid to  
10 community pharmacies if certain quality criteria are met. We believe this is  
11 significant progress, and it is important that this concept continue which will remove  
12 focus on the *number* of services a community pharmacy undertakes, to that of the  
13 quality of the service a community pharmacy undertakes. This approach is critical,  
14 given that a recent study highlighted that community services are often not related to  
15 need of the local population, and can be influenced by pharmacy ownership type.[24]  
16 The development of a quality metric will help direct funding to community  
17 pharmacies that are engaged in delivering the higher levels of service.  
18

30  
31  
32  
33  
34

35 In terms of the impact on the wider healthcare community, previous work  
36 shows that if community pharmacy services were not present, people would use  
37 alternate – and more costly – branches of the NHS, such as GP and Accident and  
38 Emergency services.[3] It is also evident that people living in more deprived areas  
39 experience higher morbidity much earlier in life, compared to people living in affluent  
40 areas – as represented by lower healthy life expectancy.[25] A study analyzing one  
41 million GP consultations in London showed that someone aged 50 years living in the  
42 most deprived quintile of English neighbourhoods consults with their GP at the same  
43 rate as someone aged 70 years in the most affluent quintile of neighbourhoods.[26]  
44 So, community pharmacy closures – particularly in deprived areas – are likely to  
45  
46  
47

1  
2  
3 increase the workload of general practice. Community pharmacies are able to reach  
4 people that other services cannot. For example, a study has shown that owing to their  
5 wider accessibility (e.g. proximity; opening times, no appointment required), many  
6 people prefer to obtain healthcare from a community pharmacy setting [27] and a  
7 qualitative study revealed some people were more likely to use a community  
8 pharmacy for healthcare advice owing to their trusting relationship they develop with  
9 the pharmacist.[28]

### 20 *Conclusion*

21  
22 Just over half of community pharmacies in England are located in clusters of  
23 three or more by ten minutes walking distance. There is also a positive trend between  
24 community pharmacy clustering and social deprivation, whereby clustering is  
25 significantly more common in areas of high deprivation. As such, arrangements for  
26 future community pharmacy funding should not solely focus upon distance from one  
27 pharmacy to another, as means of determining funding allocation, as this could  
28 penalise community pharmacies in our most deprived communities, and potentially  
29 have a negative effect on other healthcare providers, such as GP and A&E services by  
30 increasing their workload. Future funding models of community pharmacy should  
31 consider quality of healthcare and public health services provided, as well as health  
32 need of the local area.

### 46 **Contributions**

47 CB and AT designed the study, led on data interpretation, and supervised all stages of  
48 the research. KT led on the GIS modelling, and AK conducted statistical analysis. AT  
49 led the drafting of the manuscript with input from CB, KT and AK. AT is guarantor  
50 of the work.

## Acknowledgements

CB is a member of Fuse (funding reference MR/K02325X/1). Funding for Fuse comes from the British Heart Foundation, Cancer Research UK, Economic and Social Research Council, Medical Research Council, the National Institute for Health Research, under the auspices of the UK Clinical Research Collaboration, and is gratefully acknowledged (RF150334). The views expressed in this paper do not necessarily represent those of the funders or UKCRC. The funders had no role in study design, data collection and analysis, decision to publish, or preparation of the manuscript.

## Ethical approval and consent to participate

Ethical approval of this work was not required, as the study used non-patient identifiable secondary data; patients were not actively involved in this research.

## Data sharing agreement

All of our raw data is available through the open access Geo-healthcare database:

<https://collections.durham.ac.uk/files/fq977t77k#.WJSlsRicZBw>
