

BMJ Open

BMJ Open is committed to open peer review. As part of this commitment we make the peer review history of every article we publish publicly available.

When an article is published we post the peer reviewers' comments and the authors' responses online. We also post the versions of the paper that were used during peer review. These are the versions that the peer review comments apply to.

The versions of the paper that follow are the versions that were submitted during the peer review process. They are not the versions of record or the final published versions. They should not be cited or distributed as the published version of this manuscript.

BMJ Open is an open access journal and the full, final, typeset and author-corrected version of record of the manuscript is available on our site with no access controls, subscription charges or pay-per-view fees (<http://bmjopen.bmj.com>).

If you have any questions on BMJ Open's open peer review process please email info.bmjopen@bmj.com

ABSTRACT

Introduction. Hearing and vision impairments are highly prevalent among older adults and impact commonly used cognitive assessment tools for the identification of dementia. Adaptations of such tests for people with hearing or vision impairment have not been adequately validated among populations with such sensory impairment.

Methods and analysis. We propose to develop two versions of the Montreal Cognitive Assessment (MoCA) for people with acquired hearing or vision impairment, the MoCA-H and MoCA-V. The MoCA-H and MoCA-V will exclude the existing MoCA items that are presented in spoken or visual format respectively and include new suitably adapted items. 792 participants with combinations of hearing, vision and cognitive impairment will complete standard or adapted versions of the MoCA across three language sites (English, French and Greek). Development of the MoCA-H and the MoCA-V will be based on analysis of adapted and standard MoCA items following model-based development to select the combination of items for the MoCA-H and MoCA-V that provide optimal sensitivity and specificity for detection of dementia.

Ethics and dissemination. The study has received ethical approval from respective centres in the UK, France, Greece and Cyprus. The results of the study will be disseminated through peer reviewed publication, conference presentations, the study website (<https://www.sense-cog.eu/>), the SENSE-Cog Twitter account (@sense_cog) and the MoCA test website (<https://www.mocatest.org/>). The main outputs of the study will be versions of the MoCA that are appropriate for use with adults with acquired hearing or vision impairment and will contribute significantly to the clinical care of older people.

Strengths and limitations of this study

- Development and validation of adapted versions of the MoCA for people with acquired hearing or vision impairment will be completed in three languages (Greek, French and English), enabling the cultural validation of both novel and existing versions of the MoCA.
- The MoCA has previously demonstrated good reliability and validity in screening for cognitive impairment.
- Hearing and vision assessment would be carried out in participants' homes, with background noise and light levels being monitored and controlled during data collection and analysis.
- The validation includes dementia only, validation of the MoCA-H and the MoCA-V in relation to MCI is planned for the future.

Introduction

Commonly used tests for cognitive impairment mostly consist of items presented in the visual and/or auditory modality and rely on good sensory function. People with hearing or visual impairment and simulated hearing or vision impairment perform more poorly on tests of cognition than those with normal sensory function [1-6]. The confounding of cognitive tests by hearing or vision impairment may lead to false positive identification of cognitive impairment and/or over-estimation of the severity of cognitive impairment [7]. Hearing and vision impairment commonly co-occur with cognitive impairment in older adults. In two UK studies, hearing impairment was identified in 94% of people with a cognitive impairment attending a memory clinic [8] and a national survey identified visual impairment (visual acuity worse than 6/12) in 32.5% of a sample of people with dementia [9].

Previous attempts to adapt cognitive tests for people with sensory impairment involved deleting or substituting written versions of hearing-dependent items, and deleting or substituting spoken or tactile versions of vision-dependent items [10]. Unfortunately, deletion of hearing- or vision-dependent items may adversely impact sensitivity and specificity of the adapted tests. To address the need for reliable screening measures of cognitive function for people with acquired sensory impairment, we propose to develop and validate versions of the Montreal Cognitive Assessment (MoCA) [11]. The Montreal Cognitive Assessment (MoCA) is a widely used screening measure that is available free of charge and has been translated into 55 different languages. The MoCA consists of a single page, 30-item test that measures abilities in eight domains; visuospatial/executive, naming, memory, attention, language, abstraction, delayed recall and orientation. Administration time is usually less than 20 minutes. The MoCA has previously been validated in populations with vascular dementia, frontotemporal dementia [12], Parkinson's disease [13], and Alzheimer's disease (AD) [14], and has good sensitivity and specificity for the detection of both dementia and mild cognitive impairment (MCI) [11].

There have been two previous attempts to adapt the MoCA for people with hearing impairment. Lin et al. developed a computerised visual version of the MoCA with verbal instructions converted into visual instructions [15]. Adults with normal hearing (n=103) or severe-to-profound hearing loss (n=49) completed the visual version of the MoCA. All participants were screened to have normal cognitive function. Lin et al. reported no difference in computerised visual MoCA scores between those with normal hearing and

1
2
3 those with hearing impairment. There were no data about the sensitivity and specificity of
4 the computerised visual MoCA for detection of impaired cognitive function.
5
6

7 Dupuis et al. also developed a version of the MoCA for people with hearing impairment via
8 deletion of hearing-dependent items from the standard MoCA (language repetition,
9 attention to letters, digit span and delayed recall) to create the MoCA-H [4]. Dupuis et al.
10 tested adults with hearing loss (audiometric thresholds >25 dB HL; n=43) and normal
11 hearing (n=79). The MoCA-H had a higher pass rate than the standard MoCA among people
12 with hearing loss (71% versus 53%), but fewer people with hearing loss achieved passing
13 scores with proportionally adjusted cut-off scores (to account for the deleted items) versus
14 the normal hearing group (53% vs 85%). The authors concluded that the MoCA-H reduced
15 but did not eliminate poorer performance of hearing impaired versus non-impaired
16 participants.
17
18
19
20
21
22
23
24
25

26 In relation to adaptations for vision impairment, Wittich et al. re-analysed data from the
27 original validation of the MoCA to examine the effect of deleting vision-dependent items on
28 sensitivity and specificity for detection of MCI and Alzheimer's disease [3]. Wittich et al.
29 reported that the MoCA-Blind (involving deletion of four vision-dependent items; trail-
30 making, copy-cube, clock drawing, and picture naming) had increased specificity compared
31 to standard MoCA, but sensitivity was poorer for both MCI and Alzheimer's disease (63%
32 and 94% respectively).
33
34
35
36
37
38
39

40 Dupuis et al., [4] examined performance of the MoCA-Blind on the performance of
41 participants with normal vision (n=259) versus those with vision impairment (based on far
42 acuity poorer than < LogMar 0.3; n=38). There was no significant difference in MoCA-Blind
43 scores between those with normal vision and those with vision impairment.
44
45
46
47

48 There are several drawbacks with previous adaptations of the MoCA for sensory impaired
49 populations. Firstly, deleting hearing- or vision-dependent items is liable to compromise the
50 validity of the MoCA, because deletion may lead to particular cognitive domains being
51 under- or un-represented. For example, all the hearing-dependent questions that were
52 deleted in the MoCA-H [4] relate to memory. It would be preferable to substitute items in
53
54
55
56
57
58
59
60

1
2
3 an alternative sensory modality rather than deleting items [10]. Secondly, no studies have
4 validated adapted versions of the MoCA in terms of sensitivity and specificity to detect
5 cognitive impairment among people with sensory impairment.
6
7

8
9 This protocol describes development and validation of hearing- and vision-independent
10 versions of the MoCA with respect to discrimination between normal cognition and
11 dementia. Hearing and vision-independent versions of the MoCA will be developed based
12 on substitution rather than deletion of items. Furthermore, hearing- and vision-independent
13 versions of the MoCA will be validated in English, Greek and French following the translation
14 procedure outlined by Cha et al. [16]. Participants with no sensory impairment will complete
15 the standard version of the MoCA in addition to adapted items from the MoCA designed to
16 accommodate either hearing or vision impairment. Participants with hearing or vision
17 impairment will complete the respective adapted version of the MoCA for hearing or vision
18 impairment.
19
20
21
22
23
24
25

26 27 **Study aims**

28
29 The objective is to develop two amended versions of the MoCA (version 8.1) adapted to the
30 needs of people with (i) hearing and (ii) vision impairment, termed here the MoCA-H and
31 MoCA-V respectively. These versions will exclude the existing MoCA items that are
32 presented in spoken or visual format respectively, and include new suitably adapted items.
33
34 The nature and number of the substitute items are to be determined by empirical
35 investigation, but the goal is that the structure of the MoCA-H and MoCA-V will closely
36 resemble the standard MoCA in terms of the cognitive domains assessed, number of items,
37 scoring and completion time.
38
39
40
41
42
43

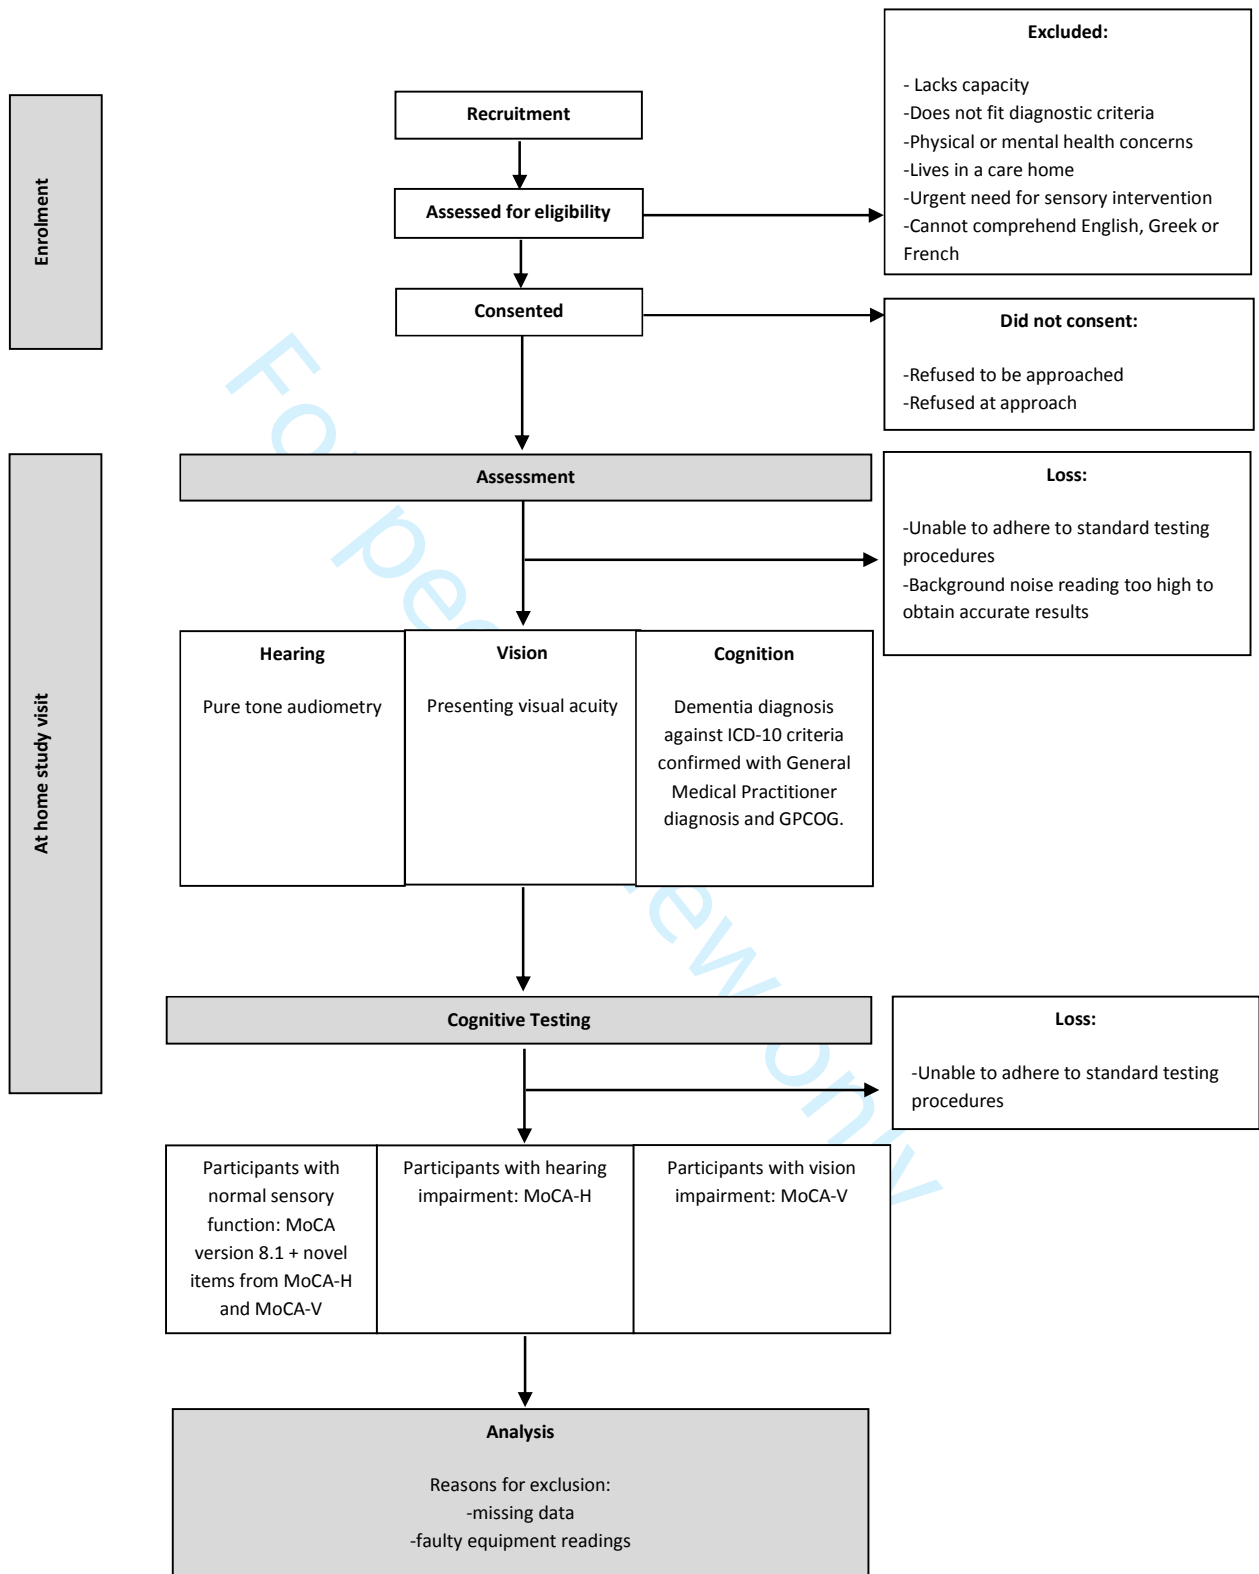

44 45 **Methods**

46 47 **Research design**

48
49 All participants will be tested for hearing, vision and cognitive function (Figure 1).
50 Participants with age associated acquired hearing or vision impairment will complete
51 adapted versions of MoCA (version 8.1) designed to account for hearing or vision
52 impairment respectively. Participants with normal sensory function will complete the
53 standard version of the MoCA (version 8.1) as well as novel items for the hearing- and
54
55
56
57
58
59
60

1
2
3 vision-independent MoCA versions. Adaptations to standard items will be designed to
4 assess the same cognitive domain of the hearing or vision dependent items. Adaptation of
5 hearing dependent items will be done by presenting written instructions and/or visual
6 versions of items requiring spoken presentation of stimuli. Adaptation of vision-dependent
7 items involves using spoken or tactile versions of items that are presented visually. Two
8 novel scales will be compiled for individuals with hearing and vision impairment respectively,
9 using the combination of items with the optimal discriminative power to differentiate
10 between normal cognitive function and cognitive impairment. An ideal solution would be
11 one in which each hearing/vision sensitive item in the MoCA is replaced by a single
12 alternative item without affecting the MoCA's domain make-up, reliability, or thresholds for
13 determining cognitive impairment. A slightly less preferred solution is one where a single
14 substitute is identified for each hearing/vision sensitive item, maintaining the domain
15 structure and reliability, but thresholds for identifying cognitive impairment are different. A
16 third and least preferred solution involves a mix of adapted items that do not replicate the
17 existing domain structure (e.g. some domains are measured with more or less items than
18 previously) with thresholds for determining cognitive impairment that are different to the
19 standard MoCA. The planned analysis (see below) is designed to assess, compare, and select
20 between these possible solutions.

Figure 1- Patient pathway through study

Participants

The study will be run in six European sites; Athens, Bordeaux, Nice, Nicosia, Bradford and Manchester. Seven hundred and ninety two older adults and their significant others/study partner will be recruited into the study in total. The sampling frame (Table 1) is designed to provide a balanced sample of participants both with and without dementia and also with and without hearing or vision impairment. One hundred and thirty two individuals will be recruited into each of six groups (Table 1). With the exception of the UK, each site will recruit 22 dyads into each of the six groups, and 132 dyads in total. Due to local service limitations, Bradford in the UK will recruit only 11 from each group (n=66 in total), and Manchester will correspondingly increase recruitment of people across all six groups (n=198).

Table 1: Overview of participant numbers in each of the study groups.

	No cognitive or sensory impairment	No cognitive impairment, hearing impairment	No cognitive impairment, visual impairment	Dementia, no sensory impairment	Dementia, hearing impairment	Dementia, vision impairment	Total
Athens	22	22	22	22	22	22	132
Bordeaux	22	22	22	22	22	22	132
Bradford	11	11	11	11	11	11	66
Nice	22	22	22	22	22	22	132
Nicosia	22	22	22	22	22	22	132
Manchester	33	33	33	33	33	33	198
							792

Inclusion criteria - Primary participant All participants will be over 60 years of age and able to provide informed consent to participate in the study. All participants will be living within the community. Participants living in residential care homes and non-domestic settings as well as individuals who do not comprehend written and spoken English, Greek or French will not be included in the study. Participants will also be excluded if they do not have an eligible study partner.

1
2
3 Criteria for the dementia group are based on ICD-10 criteria [17] operationalised as i) a
4 formal diagnosis of AD, vascular or mixed dementia confirmed via the participant's general
5 medical practitioner and ii) a score within the clinical range (a total score of zero to four) on
6 the General Practitioner Assessment of Cognition (GPCOG;[18]). If results on the GPCOG
7 examination are within the borderline range (five to eight), the GPCOG informant report will
8 be used to determine the presence or absence of dementia. A score between zero and three
9 on the informant report GPCOG indicates dementia. If a participant scores within the
10 normal range on the GPCOG (nine) and/or the GPCOG informant report (four to six), they
11 would be allocated to the 'normal cognition' group. Diagnosis of dementia is restricted to
12 AD, vascular and mixed dementia as these subtypes of dementia account for around 90% of
13 total dementia diagnoses [19]. Less common dementia types such as frontotemporal
14 dementia, Parkinson's disease and dementia with Lewy bodies will not be included due to
15 the limited statistical power to conduct analyses of dementia sub-types.
16
17
18
19
20
21
22
23
24

25
26 Determination of hearing impairment will be based upon pure-tone air conduction
27 thresholds in both ears. Individuals with a threshold of greater than 40dB HL for the
28 audiometric average of pure tone detection thresholds at 1, 2 and 4 kHz will be considered
29 to be hearing impaired. Vision impairment will be based on a measured presenting distance
30 visual acuity of less than 6/12. Any individual who has had fluctuating or recent changes in
31 hearing or visual function will be excluded.
32
33
34
35
36

37 **Inclusion criteria - Study partner** The study partner must be over 16 years of age and must
38 have known the primary participant for at least the previous 5 years in order to be able to
39 complete the informant version of the GPCOG.
40
41
42
43

44 **Sample Size Calculation**

45
46 The sample size is based on achieving acceptably precise estimates of the sensitivity and
47 specificity of the adapted tools for detecting dementia, separately for people with hearing
48 impairment and with vision impairment in relation to the MoCA-H and MoCA-V respectively.
49 The sample of 264 individuals (132 with dementia and 132 without) within the MoCA-H and
50 MoCA-V groups, will enable estimation of the sensitivity to detect dementia and specificity
51 to exclude normal cognition to within 9% of the true value (95% confidence interval). After
52
53
54
55
56
57
58
59
60

1
2
3 combining across all impairment groups, sensitivity and specificity for each of the three
4 language versions will also be estimated to within 9%.

6 7 **Recruitment**

8
9 Participants will be recruited from ophthalmology and audiology services, memory clinics,
10 volunteer databases and the general community. In the UK, participants will also be
11 recruited through the 'Join Dementia Research' volunteer database [20]. Sites in France,
12 Greece and Cyprus will develop their own recruitment strategies in accordance with local
13 service provision. The member of the clinical care team at each recruitment site will provide
14 information about the study to potential participants. Potential participants would then
15 contact the research team to arrange participation. Participants will be given a minimum of
16 24 hours to decide whether or not they wish to participate in the study.
17
18
19
20
21
22
23

24 **Consent and Testing Procedures**

25
26 All study visits will take place at participants' homes. At the start of the initial study visit,
27 capacity to consent will be evaluated and written informed consent obtained from both the
28 individual participating and their study partner. All individuals taking consent will have
29 received training in checking capacity in accordance with the Mental Capacity Act (2005) [21]
30 or relevant local guidance in other sites. Consent will be considered on an on-going basis. If
31 more than one study visit is required, willingness to continue will be discussed at the start of
32 each visit with both the older adult and their significant other.
33
34
35
36
37
38

39 Following informed written consent, participants would complete the GPCOG and study
40 partners would complete the GPCOG informant version. Participants would then complete
41 hearing and vision assessments before completing the MoCA. Participants in the 'vision
42 impairment' groups would complete the MoCA-V, participants in the 'hearing impairment'
43 group would complete the MoCA-H. Participants with normal sensory function would
44 complete the standard MoCA as well as the novel items from both the MoCA-V and the
45 MoCA-H. The MoCA-H and the MoCA-V will follow standard MoCA testing procedure as
46 closely as possible.
47
48
49
50
51
52
53

54 All data collectors in the study will be trained in Good Clinical Practice [22] and will have
55 received relevant training on the administration of the screening measures and cognitive
56
57
58
59

1
2
3 tests. Individuals will also have received training on assessing capacity in older adults
4 consistent with the UK's Mental Capacity Act (2005) [21], or with relevant local legislation
5 at partner sites. Any individual deemed to be lacking in capacity will not be included in the
6 study. All data transferred between sites will be encrypted and no individual will be
7 identifiable from the stored data. Identifiable patient information will be stored in a locked
8 cabinet which will only be accessible to research members at the site of the data collection.
9 Data will be monitored as it comes in for consistency. Data integrity checks will be
10 performed whereby 5% of all data will be checked against source documents for accuracy.
11
12
13
14
15
16

17 **Data statement**

18
19 Data will be held in the University of Manchester institutional repository. Published outputs
20 will include a Digital Object Identifier (DOI) number, and fully anonymised data would be
21 publicly available.
22
23
24
25

26 **Test-retest**

27
28 Five participants from each of the study groups (per language site; n=30) will be invited to
29 perform a retest of the study measures two to four weeks after the initial testing. At each
30 site, following a run-in period of ten participants, consecutive participants will be invited to
31 undertake a re-test until the target of five has been achieved.
32
33
34
35

36 **Assessments**

37
38 Hearing and vision - hearing testing will involve pure tone audiometry using a R07A
39 Screening Portable Audiometer (Kamplex Limited, London), using audiocup headphones
40 (Amplivox, Eden Prairie MN) to minimise interference from background noise. A KM6 Sound
41 level meter (Kamplex Limited, London) will be used to measure background noise to ensure
42 that noise levels are below those recommended based on American National Standards
43 Institute standards [23]. Testing will begin with the self-reported better ear should the
44 participant have one. Participants would be tested without hearing aids, if they use them.
45 Vision testing involves assessment of presenting visual acuity (i.e. assessed with glasses that
46 are usually worn for distance viewing) with LED 930 illuminated 3 meter charts (Precision
47 Vision, Woodstock IL). Illuminated charts will be used so that testing can be carried out
48
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3 without additional lighting in order to homogenise light levels within the home
4 environments.
5

6
7 GPCOG – the GPCOG is intended as a screening instrument for dementia in primary care
8 settings. The GPCOG and GPCOG informant report versions take less than 4 minutes to
9 administer. The GPCOG is at least as effective as the Mini-Mental State Examination [24] in
10 identifying dementia [25]. The GPCOG is not impacted by the cultural or linguistic
11 background of the test-taker [26] making it an ideal reference for the present cross-national
12 validation study.
13
14
15
16

17 **Adaption of MoCA (version 8.1) for people with acquired hearing impairment (MoCA-H)**

18
19
20
21 Adaptation involved presentation of instructions and stimuli from the MoCA items in
22 written rather than spoken format (Table 1). Test-takers will be asked to read the written
23 instructions aloud to the examiner. Research using written versions of cognitive tests has
24 previously demonstrated similar performance to verbal versions [1, 15, 27]. Two items –
25 ‘language’ and ‘attention to letters’ required substitution with alternative items. The
26 ‘language’ item in the MoCA involves repetition of spoken sentences. Alternative MoCA-H
27 ‘language’ items involve constructing sentences from a list of visually presented words. The
28 ‘attention to letters’ item in the MoCA requires test-takers to tap their finger in response to
29 hearing an ‘A’ in a string of letters that are read aloud. The MoCA-H substitute ‘attention to
30 letters’ items require participants to read the numbers that are in circles as opposed to
31 squares in a string of numbers bordered by different shapes.
32
33
34
35
36
37
38
39

40 **Adaptation of the MoCA (version 8.1) for people with acquired vision impairments (MoCA-** 41 **V)**

42
43
44
45 Adaptation of the MoCA for people with vision impairment involved substitution of the first
46 two sections of the MoCA, which rely on good vision (trail making test [TMT], copy cube,
47 clock draw and naming task; Table 1). These visually-dependent items were substituted for
48 analogous tasks in the auditory domain: visual TMT was substituted with the oral TMT [28].
49 The clock draw task was substituted with the Verbal Clock Test[29]. Both the oral TMT and
50 the Verbal Clock Test are measures of executive function that were designed to remove
51 confounding effects of impaired vision and motor skills on performance and have
52
53
54
55
56
57
58
59
60

1
2
3 established validity and reliability. The 'copy cube' task was substituted with questions
4 about the shape of a cube. The 'naming' task was substituted with object identification
5 based on touch. The latter two substitutions were novel items developed by the authors.

Statistical analysis

The following describes the statistical analysis plan for development of the MoCA-H and the MoCA-V, based on replacing the hearing/vision-sensitive items with adapted items (see Table 1). As a first step, each MoCA-H and MoCA-V item will be assessed for the following:

1. Discrimination: no more than 80% of participants achieving the same score.
2. Feasibility: no more than 5% missing responses
3. Redundancy: correlations with other items > 0.75
4. Independence from hearing/vision ability: degree of association with level of hearing impairment, based on comparison between item performance between non-sensory impaired groups and hearing/vision impaired groups.
5. Comparability between versions: where relevant, we will compare performance (% achievement) on the original MoCA item and the adapted version(s) of the item. For the novel items this will be a within-person comparison based on the data from the non-impaired subgroups collected specifically for this purpose. For other adapted items (e.g. where the adaptation involved the provision of written instructions) it will be a comparison between the appropriate non-impaired and sensory-impaired subgroups.

Substitution-based model development

The substitution of items with written rather than spoken instructions has the potential to change scores. Therefore the substitution-based analysis will focus on the reliability and score characteristics of the overall instrument, rather than of the individual question items. We will begin by including all adapted items in the instrument scoring and examine the distribution of overall scores, reliability, and optimum cognitive impairment threshold scores together with area-under-the-curve (AUC), sensitivity and specificity (via ROC analysis). Focusing on the domains where we have multiple alternative adapted items, we will then use a stepwise “backwards elimination” method to remove items from these domains one-by-one, in a way that maximises the AUC (as an index of overall predictive performance) without unduly affecting the tool’s reliability coefficient. Where there is no clear choice of item for removal, we will also take into account each item’s performance indices from the item analysis.

1
2
3 This stepwise procedure will be continued until the adapted instrument has precisely one-
4 to-one substitution of adapted items for original items in every domain throughout, or until
5 it is not possible to remove further items without seriously undermining the level of
6 reliability. The performance measures for the resulting instrument will then be computed.
7
8
9

10 **Exploratory-based model development**

11
12 We will also conduct a purely exploratory analysis to identify a version of the MoCA-H and
13 the MoCA-V with the highest degree of discriminative ability between people with and
14 without dementia, regardless of domain make-up. This analysis will follow more standard
15 “classical” procedures for scale development. From the results of the item analysis, items
16 showing good discrimination, feasibility, low redundancy, comparability, and independence
17 from hearing or vision ability will be retained. Items poor on any of these criteria will be
18 considered for removal prior to further analysis. In the case of the MoCA-H for example, we
19 anticipate that the 4 existing MoCA hearing-sensitive items will demonstrate association
20 with hearing impairment, but will also check and if necessary remove additional items.
21
22
23
24
25
26
27
28

29 Following the removal of poorly performing items, we will apply logistic regression to
30 identify the subset of remaining items that best predicts each participant’s cognitive status
31 (i.e. dementia/no dementia). The analysis will be based on the 264 participants with
32 hearing/vision impairment and use a step-wise backwards elimination method for removal
33 of items from the regression model. At the first step all items that passed the item analysis
34 stage will be entered as a group. At each subsequent step the item that contributes least to
35 the explanatory power of the model (the item with the largest p -value) will be removed.
36 This will continue until all items remaining in the model have a p -value of 0.1 or lower. We
37 use a high p -value (10%) at this stage for inclusivity, prior to further assessment.
38
39
40
41
42
43
44
45

46 For verification we will then repeat this analysis, but using stepwise entry of items in place
47 of stepwise removal. A final selection of items will be decided through comparison of the
48 two models: where there are differences a final decision will be made taking account of any
49 relevant theoretical and statistical considerations.
50
51
52

53 **Comparison of models.** As a final step we will compare the resulting models from the
54 substitution-based and exploratory approaches to constructing the MoCA-H and the MoCA-
55
56
57
58
59
60

1
2
3 V. We will compute participant scores on each model by totalling across the correctly
4 answered items, as per the procedure for the standard MoCA. The models will then be
5 compared on a range of key performance indices including AUC, internal consistency
6 (Cronbach's alpha), test-retest reliability (intra-cluster reliability co-efficient), sensitivity and
7 specificity, and optimum cut-point for dementia diagnosis. A choice of the final
8 recommended version of the MoCA-H will then be made on the basis of this comparison
9 along with relevant clinical considerations. Assessment at participants' homes may facilitate
10 performance on the 'orientation to place' questions, reduce stress and impact on the total
11 score. Therefore comparability of scores would be tested with reference to existing MoCA
12 normative data.
13
14

15
16 The result of the above analytical procedures will be finalised versions of the MoCA-H and
17 MoCA-V instruments, in each of three languages (English, French, Greek) together with
18 recommended threshold values for detecting dementia and measures of internal
19 consistency and test-retest reliability.

Discussion

The current paper describes the protocol for the development and validation of versions of the MoCA (version 8.1) [11] for the identification of dementia within populations of adults with acquired hearing or vision impairment. Six participant groups will complete the MoCA or a version of the MoCA adapted to accommodate either vision or hearing impairment – the MoCA-H and the MoCA-V. Through a process of item and predictive analyses, we will determine the combinations of items with the best balance of discriminative power relative to gold standard diagnostic criteria, clinical validity and utility, and reliability, within groups of adults with hearing or vision impairment.

The development of the MoCA-H and the MoCA-V draws on the diagnostic strengths of the previously well-validated MoCA. It is anticipated that through item substitution rather than the deletion of items, the MoCA-H for people with hearing impairment and the MoCA-V for people with vision impairment will have superior validity and reliability compared to previously adapted alternative measures [10].

Study outputs will include adaptations of the MoCA suitable for use in people with hearing and vision impairments. In addition to this, the study will provide validation data on Greek and French versions of the MoCA (version 8.1) in populations without sensory impairment.

Author contributions: IL and PD are responsible for the overall development of an ethically sound protocol. PD, KG, AP, SS, WKY and ZN developed the MoCA-H and MoCA-V. PD, AP and DR designed the validation study and DR planned the analyses. All authors contributed to the drafting, critical revision and final approval of the document.

Funding statement: This work was supported by the European Union's Horizon 2020 research and innovation programme under grant agreement number 668648.

ABSTRACT

Introduction. Hearing and vision impairments are highly prevalent among older adults and impact commonly used cognitive assessment tools for the identification of dementia. Adaptations of such tests for people with hearing or vision impairment have not been adequately validated among populations with such sensory impairment.

Methods and analysis. We will develop two versions of the Montreal Cognitive Assessment (MoCA) for people with acquired hearing or vision impairment, the MoCA-H and MoCA-V. The MoCA-H and MoCA-V will exclude the existing MoCA items that are presented in spoken or visual format respectively and include new suitably adapted items. Participants (n = 792) with combinations of hearing, vision and cognitive impairment will complete standard or adapted versions of the MoCA across three language sites (English, French and Greek). Development of the MoCA-H and the MoCA-V will be based on analysis of adapted and standard MoCA items following model-based development to select the combination of items for the MoCA-H and MoCA-V that provide optimal sensitivity and specificity for detection of dementia.

Ethics and dissemination. The study has received ethical approval from respective centres in the UK, France, Greece and Cyprus. The results of the study will be disseminated through peer reviewed publication, conference presentations, the study website (<https://www.sense-cog.eu/>), the SENSE-Cog Twitter account (@sense_cog) and the MoCA test website (<https://www.mocatest.org/>). The main outputs of the study will be versions of the MoCA that are appropriate for use with adults with acquired hearing or vision impairment and will contribute significantly to the clinical care of older people.

Strengths and limitations of this study

- Development and validation of adapted versions of the MoCA for people with acquired hearing or vision impairment will be completed in three languages (Greek, French and English), enabling the cultural validation of both novel and existing versions of the MoCA.
- The MoCA has been shown to have good reliability and validity in screening for cognitive impairment.
- Hearing and vision assessment would be carried out in participants' homes, with background noise and light levels being monitored and controlled during data collection and analysis.
- The validation includes dementia only, validation of the MoCA-H and the MoCA-V in relation to MCI is planned for the future.

Introduction

Commonly used tests for cognitive impairment mostly consist of items presented in the visual and/or auditory modality and rely on good sensory function. People with hearing or visual impairment and simulated hearing or vision impairment perform more poorly on tests of cognition than those with normal sensory function [1-6]. The confounding of cognitive tests by hearing or vision impairment may lead to false positive identification of cognitive impairment and/or over-estimation of the severity of cognitive impairment [7]. Hearing and vision impairment commonly co-occur with cognitive impairment in older adults. In two UK studies, hearing impairment was identified in 94% of people with a cognitive impairment attending a memory clinic [8] and a national survey identified visual impairment (visual acuity worse than 6/12) in 32.5% of a sample of people with dementia [9].

Previous attempts to adapt cognitive tests for people with sensory impairment involved deleting or substituting written versions of hearing-dependent items, and deleting or substituting spoken or tactile versions of vision-dependent items [10]. Unfortunately, deletion of hearing- or vision-dependent items may adversely impact sensitivity and specificity of the adapted tests. To address the need for reliable screening measures of cognitive function for people with acquired sensory impairment, we propose to develop and validate versions of the Montreal Cognitive Assessment (MoCA) [11]. The Montreal Cognitive Assessment (MoCA) is a widely used screening measure that is available free of charge and has been translated into 55 different languages. The MoCA consists of a single page, 30-item test that measures abilities in eight domains; visuospatial/executive, naming, memory, attention, language, abstraction, delayed recall and orientation. Administration time is usually less than 20 minutes. The MoCA has previously been validated in populations with vascular dementia, frontotemporal dementia [12], Parkinson's disease [13], and Alzheimer's disease (AD) [14], and has good sensitivity and specificity for the detection of both dementia and mild cognitive impairment (MCI) [11].

There have been two previous attempts to adapt the MoCA for people with hearing impairment. Lin et al. developed a computerised visual version of the MoCA with verbal instructions converted into visual instructions [15]. Adults with normal hearing (n=103) or severe-to-profound hearing loss (n=49) completed the visual version of the MoCA. All

1
2
3 participants were screened to have normal cognitive function. Lin et al. reported no
4 difference in computerised visual MoCA scores between those with normal hearing and
5 those with hearing impairment. There were no data about the sensitivity and specificity of
6 the computerised visual MoCA for detection of impaired cognitive function.
7
8
9

10
11 Dupuis et al. also developed a version of the MoCA for people with hearing impairment via
12 deletion of hearing-dependent items from the standard MoCA (language repetition,
13 attention to letters, digit span and delayed recall) to create the MoCA-H [4]. Dupuis et al.
14 tested adults with hearing loss (audiometric thresholds >25 dB HL; n=43) and normal
15 hearing (n=79). The MoCA-H had a higher pass rate than the standard MoCA among people
16 with hearing loss (71% versus 53%), but fewer people with hearing loss achieved passing
17 scores with proportionally adjusted cut-off scores (to account for the deleted items) versus
18 the normal hearing group (53% vs 85%). The authors concluded that the MoCA-H reduced
19 but did not eliminate poorer performance of hearing impaired versus non-impaired
20 participants.
21
22
23
24
25
26
27
28
29
30

31 In relation to adaptations for vision impairment, Wittich et al. re-analysed data from the
32 original validation of the MoCA to examine the effect of deleting vision-dependent items on
33 sensitivity and specificity for detection of MCI and Alzheimer's disease [3]. Wittich et al.
34 reported that the MoCA-Blind (involving deletion of four vision-dependent items; trail-
35 making, copy-cube, clock drawing, and picture naming) had increased specificity compared
36 to standard MoCA, but sensitivity was poorer for both MCI and Alzheimer's disease (63%
37 and 94% respectively).
38
39
40
41
42
43
44
45

46 Dupuis et al., [4] examined performance of the MoCA-Blind on the performance of
47 participants with normal vision (n=259) versus those with vision impairment (based on far
48 acuity poorer than < LogMar 0.3; n=38). There was no significant difference in MoCA-Blind
49 scores between those with normal vision and those with vision impairment.
50
51
52
53

54
55 There are several drawbacks with previous adaptations of the MoCA for sensory impaired
56 populations. Firstly, deleting hearing- or vision-dependent items is liable to compromise the
57 validity of the MoCA, because deletion may lead to particular cognitive domains being
58
59
60

1
2
3 under- or un-represented. For example, all the hearing-dependent questions that were
4 deleted in the MoCA-H [4] relate to memory. It would be preferable to substitute items in
5 an alternative sensory modality rather than deleting items [10]. Secondly, no studies have
6 validated adapted versions of the MoCA in terms of sensitivity and specificity to detect
7 cognitive impairment among people with sensory impairment.
8
9
10
11

12
13 This protocol describes development and validation of hearing- and vision-independent
14 versions of the MoCA with respect to discrimination between normal cognition and
15 dementia. Hearing and vision-independent versions of the MoCA will be developed based
16 on substitution rather than deletion of items. Furthermore, hearing- and vision-independent
17 versions of the MoCA will be validated in English, Greek and French following the translation
18 procedure outlined by Cha et al. [16]. Participants with no sensory impairment will complete
19 the standard version of the MoCA in addition to adapted items from the MoCA designed to
20 accommodate either hearing or vision impairment. Participants with hearing or vision
21 impairment will complete the respective adapted version of the MoCA for hearing or vision
22 impairment.
23
24
25
26
27
28
29
30

31 **Study aims**

32
33 The objective is to develop two amended versions of the MoCA (version 8.1) adapted to the
34 needs of people with (i) hearing and (ii) vision impairment, termed here the MoCA-H and
35 MoCA-V respectively. These versions will exclude the existing MoCA items that are
36 presented in spoken or visual format respectively, and include new suitably adapted items.
37 The nature and number of the substitute items are to be determined by empirical
38 investigation, but the goal is that the structure of the MoCA-H and MoCA-V will closely
39 resemble the standard MoCA in terms of the cognitive domains assessed, number of items,
40 scoring and completion time.
41
42
43
44
45
46
47
48
49

50 **Methods**

51 **Research design**

52
53 All participants will be tested for hearing, vision and cognitive function (Figure 1).
54 Participants with age associated acquired hearing or vision impairment will complete
55 adapted versions of MoCA (version 8.1) designed to account for hearing or vision
56
57
58
59
60

1
2
3 impairment respectively. Participants with normal sensory function will complete the
4 standard version of the MoCA (version 8.1) as well as novel items for the hearing- and
5 vision-independent MoCA versions. Adaptations to standard items will be designed to
6 assess the same cognitive domain of the hearing or vision dependent items. Adaptation of
7 hearing dependent items will be done by presenting written instructions and/or visual
8 versions of items requiring spoken presentation of stimuli. Adaptation of vision-dependent
9 items involves using spoken or tactile versions of items that are presented visually. Two
10 novel scales will be compiled for individuals with hearing and vision impairment respectively,
11 using the combination of items with the optimal discriminative power to differentiate
12 between normal cognitive function and cognitive impairment. An ideal solution would be
13 one in which each hearing/vision sensitive item in the MoCA is replaced by a single
14 alternative item without affecting the MoCA's domain make-up, reliability, or thresholds for
15 determining cognitive impairment. A slightly less preferred solution is one where a single
16 substitute is identified for each hearing/vision sensitive item, maintaining the domain
17 structure and reliability, but thresholds for identifying cognitive impairment are different. A
18 third and least preferred solution involves a mix of adapted items that do not replicate the
19 existing domain structure (e.g. some domains are measured with more or less items than
20 previously) with thresholds for determining cognitive impairment that are different to the
21 standard MoCA. The planned analysis (see below) is designed to assess, compare, and select
22 between these possible solutions.

(Figure 1 here)

Participants

The study will be run in six European sites; Athens, Bordeaux, Nice, Nicosia, Bradford and Manchester. Seven hundred and ninety two older adults and their significant others/study partner will be recruited into the study in total. The sampling frame (Table 1) is designed to provide a balanced sample of participants both with and without dementia and also with and without hearing or vision impairment. One hundred and thirty two individuals will be recruited into each of six groups (Table 1). With the exception of the UK, each site will recruit 22 dyads into each of the six groups, and 132 dyads in total. Due to local service limitations, Bradford in the UK will recruit only 11 from each group (n=66 in total), and Manchester will correspondingly increase recruitment of people across all six groups (n=198).

Table 1: Overview of participant numbers in each of the study groups.

	No cognitive or sensory impairment	No cognitive impairment, hearing impairment	No cognitive impairment, visual impairment	Dementia, no sensory impairment	Dementia, hearing impairment	Dementia, vision impairment	Total
Athens	22	22	22	22	22	22	132
Bordeaux	22	22	22	22	22	22	132
Bradford	11	11	11	11	11	11	66
Nice	22	22	22	22	22	22	132
Nicosia	22	22	22	22	22	22	132
Manchester	33	33	33	33	33	33	198
							792

Inclusion criteria - Primary participant All participants will be over 60 years of age and able to provide informed consent to participate in the study. All participants will be living within the community. Participants living in residential care homes and non-domestic settings as

1
2
3 individuals who do not comprehend written and spoken English, Greek or French, as well as
4 those with dual sensory impairment (i.e. both hearing and vision impairment, according to
5 the definitions of hearing and vision impairment for the study) and those who are culturally
6 Deaf or blind will not be included in the study. Participants will also be excluded if they do
7 not have an eligible study partner.
8
9
10
11
12

13 Criteria for the dementia group are based on ICD-10 criteria [17] operationalised as i) a
14 formal diagnosis of AD, vascular or mixed dementia confirmed via the participant's general
15 medical practitioner and ii) a score within the clinical range (a total score of zero to four) on
16 the General Practitioner Assessment of Cognition (GPCOG;[18]). If results on the GPCOG
17 examination are within the borderline range (five to eight), the GPCOG informant report will
18 be used to determine the presence or absence of dementia. A score between zero and three
19 on the informant report GPCOG indicates dementia. If a participant scores within the
20 normal range on the GPCOG (nine) and/or the GPCOG informant report (four to six), they
21 would be allocated to the 'normal cognition' group. Diagnosis of dementia is restricted to
22 AD, vascular and mixed dementia as these subtypes of dementia account for around 90% of
23 total dementia diagnoses [19]. Less common dementia types such as frontotemporal
24 dementia, Parkinson's disease and dementia with Lewy bodies will not be included due to
25 the limited statistical power to conduct analyses of dementia sub-types.
26
27
28
29
30
31
32
33
34
35
36
37

38 Determination of hearing impairment will be based upon pure-tone air conduction
39 thresholds in both ears. Individuals with a threshold of greater than 40dB HL for the
40 audiometric average of pure tone detection thresholds at 1, 2 and 4 kHz will be considered
41 to be hearing impaired. Vision impairment will be based on a measured presenting distance
42 visual acuity of less than 6/12. Any individual who has had fluctuating or recent changes in
43 hearing or visual function will be excluded.
44
45
46
47
48

49 **Inclusion criteria - Study partner** The study partner must be over 16 years of age and must
50 have known the primary participant for at least the previous 5 years in order to be able to
51 complete the informant version of the GPCOG.
52
53
54
55
56

57 **Sample Size Calculation**

58
59
60

1
2
3 The sample size is based on achieving acceptably precise estimates of the sensitivity and
4 specificity of the adapted tools for detecting dementia, separately for people with hearing
5 impairment and with vision impairment in relation to the MoCA-H and MoCA-V respectively.
6
7 The sample of 264 individuals (132 with dementia and 132 without) within the MoCA-H and
8 MoCA-V groups, will enable estimation of the sensitivity to detect dementia and specificity
9 to exclude normal cognition to within 9% of the true value (based on the exact 95%
10 confidence interval for a binary variable, calculated using Stata version 15). After combining
11 across all impairment groups, sensitivity and specificity for each of the three language
12 versions will also be estimated to within 9%.

20 **Recruitment**

21
22
23 Participants will be recruited from ophthalmology and audiology services, memory clinics,
24 volunteer databases and the general community. In the UK, participants will also be
25 recruited through the 'Join Dementia Research' volunteer database [20]. Sites in France,
26 Greece and Cyprus will develop their own recruitment strategies in accordance with local
27 service provision. The member of the clinical care team at each recruitment site will provide
28 information about the study to potential participants. Potential participants would then
29 contact the research team to arrange participation. Participants will be given a minimum of
30 24 hours to decide whether or not they wish to participate in the study.

38 **Consent and Testing Procedures**

39
40
41 All study visits will take place at participants' homes. At the start of the initial study visit,
42 capacity to consent will be evaluated and written informed consent obtained from both the
43 individual participating and their study partner. All individuals taking consent will have
44 received training in checking capacity in accordance with the legal requirements for
45 conducting research in each country (i.e. the Mental Capacity Act (2005) in the UK, the Code
46 de la santé publique in France, Article 47 of the Hospital Law of 1992 (2071) in Greece and
47 article 14 of Law No. 1 (I) 2005 in Cyprus [21]). Consent will be considered on an on-going
48 basis. If more than one study visit is required, willingness to continue will be discussed at
49 the start of each visit with both the older adult and their significant other.

1
2
3 Following informed written consent, participants would complete the GPCOG and study
4 partners would complete the GPCOG informant version. Participants would then complete
5 hearing and vision assessments before completing the MoCA. Participants in the 'vision
6 impairment' groups would complete the MoCA-V, participants in the 'hearing impairment'
7 group would complete the MoCA-H. Participants with normal sensory function would
8 complete the standard MoCA as well as the novel items from both the MoCA-V and the
9 MoCA-H. The MoCA-H and the MoCA-V will follow standard MoCA testing procedure as
10 closely as possible.
11
12
13
14
15
16
17

18 All data collectors in the study will be trained in Good Clinical Practice [22] and will have
19 received relevant training on the administration of the screening measures and cognitive
20 tests. Individuals will also have received training on assessing capacity in older adults
21 consistent with relevant local legislation at partner sites. Any individual deemed to be
22 lacking in capacity will not be included in the study. All data transferred between sites will
23 be encrypted and no individual will be identifiable from the stored data. Identifiable patient
24 information will be stored in a locked cabinet which will only be accessible to research
25 members at the site of the data collection. Data will be monitored as it comes in for
26 consistency. Data integrity checks will be performed whereby 5% of all data will be checked
27 against source documents for accuracy.
28
29
30
31
32
33
34
35
36
37

38 **Patient and Public Involvement**

39
40 Four research user groups (RUGs) of people with dementia with age-related hearing and/or vision
41 impairment and their support people were established in the UK, France, Cyprus and Greece to
42 provide advice on the research [23]. Research awareness training was provided to support
43 involvement (based on the EQUIP training package; [24]). RUGs were consulted with respect to i)
44 recruitment materials and study documentation and ii) a dissemination plan for the research.
45 Recruitment materials were revised according to RUG feedback to improve readability. The
46 dissemination plan included face to face public engagement events and YouTube video summaries
47 following suggestions from the RUGs.

1
2
3 Data will be held in the University of Manchester institutional repository. Published outputs
4 will include a Digital Object Identifier (DOI) number, and fully anonymised data would be
5 publicly available.
6
7
8

9 **Test-retest**

10
11 Five participants from each of the study groups (per language site; n=30) will be invited to
12 perform a retest of the study measures two to four weeks after the initial testing. At each
13 site, following a run-in period of ten participants, consecutive participants will be invited to
14 undertake a re-test until the target of five has been achieved.
15
16
17
18

19 **Assessments**

20
21 Hearing and vision - hearing testing will involve pure tone audiometry using a R07A
22 Screening Portable Audiometer (Kamplex Limited, London), using audiocup headphones
23 (Amplivox, Eden Prairie MN) to minimise interference from background noise. A KM6 Sound
24 level meter (Kamplex Limited, London) will be used to measure background noise to ensure
25 that noise levels are below those recommended based on American National Standards
26 Institute standards [25]. Testing will begin with the self-reported better ear should the
27 participant have one. Participants would be tested without hearing aids, if they use them.
28 Vision testing involves assessment of presenting visual acuity (i.e. assessed with glasses that
29 are usually worn for distance viewing) with LED 930 illuminated 3 meter charts (Precision
30 Vision, Woodstock IL). Illuminated charts will be used so that testing can be carried out
31 without additional lighting in order to homogenise light levels within the home
32 environments.
33

35
36
37
38
39
40
41
42
43
44

45
46 GPCOG – the GPCOG is intended as a screening instrument for dementia in primary care
47 settings. The GPCOG and GPCOG informant report versions take less than 4 minutes to
48 administer. The GPCOG is at least as effective as the Mini-Mental State Examination [26] in
49 identifying dementia [27]. The GPCOG is not impacted by the cultural or linguistic
50 background of the test-taker (although it has not been specifically validated with French or
51 Greek populations) [28] making it an ideal reference for the present cross-national
52 validation study.
53
54
55
56
57
58

59 **Adaption of MoCA (version 8.1) for people with acquired hearing impairment (MoCA-H)**

1
2
3 Adaptation involved presentation of instructions and stimuli from the MoCA items in
4 written rather than spoken format (Table 1). Test-takers will be asked to read the written
5 instructions aloud to the examiner. Research using written versions of cognitive tests has
6 previously demonstrated similar performance to verbal versions [1, 15, 29]. Two items –
7 ‘language’ and ‘attention to letters’ required substitution with alternative items. The
8 ‘language’ item in the MoCA involves repetition of spoken sentences. Alternative MoCA-H
9 ‘language’ items involve constructing sentences from a list of visually presented words. The
10 ‘attention to letters’ item in the MoCA requires test-takers to tap their finger in response to
11 hearing an ‘A’ in a string of letters that are read aloud. The MoCA-H substitute ‘attention to
12 letters’ items require participants to read the numbers that are in circles as opposed to
13 squares in a string of numbers bordered by different shapes.

22
23

24 **Adaptation of the MoCA (version 8.1) for people with acquired vision impairments (MoCA-** 25 **v)** 26

27
28
29 Adaption of the MoCA for people with vision impairment involved substitution of the first
30 two sections of the MoCA, which rely on good vision (trail making test [TMT], copy cube,
31 clock draw and naming task; Table 1). These visually-dependent items were substituted for
32 analogous tasks in the auditory domain: visual TMT was substituted with the oral TMT [30].
33 The clock draw task was substituted with the Verbal Clock Test[31]. Both the oral TMT and
34 the Verbal Clock Test are measures of executive function that were designed to remove
35 confounding effects of impaired vision and motor skills on performance and have
36 established validity and reliability. The ‘copy cube’ task was substituted with questions
37 about the shape of a cube. The ‘naming’ task was substituted with object identification
38 based on touch. The latter two substitutions were novel items developed by the authors.

Statistical analysis

The following describes the statistical analysis plan for development of the MoCA-H and the MoCA-V, based on replacing the hearing/vision-sensitive items with adapted items (see Table 1). As a first step, each MoCA-H and MoCA-V item will be assessed for the following:

1. Discrimination: no more than 80% of participants achieving the same score.
2. Feasibility: no more than 5% missing responses
3. Redundancy: correlations with other items > 0.75
4. Independence from hearing/vision ability: degree of association with level of hearing impairment, based on comparison between item performance between non-sensory impaired groups and hearing/vision impaired groups.
5. Comparability between versions: where relevant, we will compare performance (% achievement) on the original MoCA item and the adapted version(s) of the item. For the novel items this will be a within-person comparison based on the data from the non-impaired subgroups collected specifically for this purpose. For other adapted items (e.g. where the adaptation involved the provision of written instructions) it will be a comparison between the appropriate non-impaired and sensory-impaired subgroups.

Substitution-based model development

The substitution of items with written rather than spoken instructions has the potential to change scores. Therefore the substitution-based analysis will focus on the reliability and score characteristics of the overall instrument, rather than of the individual question items. We will begin by including all adapted items in the instrument scoring and examine the distribution of overall scores, reliability, and optimum cognitive impairment threshold scores together with area-under-the-curve (AUC), sensitivity and specificity (via ROC analysis). Focusing on the domains where we have multiple alternative adapted items, we will then use a stepwise “backwards elimination” method to remove items from these domains one-by-one, in a way that maximises the AUC (as an index of overall predictive performance) without unduly affecting the tool’s reliability coefficient. Where there is no clear choice of item for removal, we will also take into account each item’s performance indices from the item analysis.

1
2
3 This stepwise procedure will be continued until the adapted instrument has precisely one-
4 to-one substitution of adapted items for original items in every domain throughout, or until
5 it is not possible to remove further items without seriously undermining the level of
6 reliability. The performance measures for the resulting instrument will then be computed.
7
8
9

10 **Exploratory-based model development**

11
12 We will also conduct a purely exploratory analysis to identify a version of the MoCA-H and
13 the MoCA-V with the highest degree of discriminative ability between people with and
14 without dementia, regardless of domain make-up. This analysis will follow more standard
15 “classical” procedures for scale development. From the results of the item analysis, items
16 showing good discrimination, feasibility, low redundancy, comparability, and independence
17 from hearing or vision ability will be retained. Items poor on any of these criteria will be
18 considered for removal prior to further analysis. In the case of the MoCA-H for example, we
19 anticipate that the 4 existing MoCA hearing-sensitive items will demonstrate association
20 with hearing impairment, but will also check and if necessary remove additional items.
21
22
23
24
25
26
27
28
29

30
31 Following the removal of poorly performing items, we will apply logistic regression to
32 identify the subset of remaining items that best predicts each participant’s cognitive status
33 (i.e. dementia/no dementia). The analysis will be based on the 264 participants with
34 hearing/vision impairment and use a step-wise backwards elimination method for removal
35 of items from the regression model. At the first step all items that passed the item analysis
36 stage will be entered as a group. At each subsequent step the item that contributes least to
37 the explanatory power of the model (the item with the largest p -value) will be removed.
38 This will continue until all items remaining in the model have a p -value of 0.1 or lower. We
39 use a high p -value (10%) at this stage for inclusivity, prior to further assessment.
40
41
42
43
44
45
46
47
48

49 For verification we will then repeat this analysis, but using stepwise entry of items in place
50 of stepwise removal. A final selection of items will be decided through comparison of the
51 two models: where there are differences a final decision will be made taking account of any
52 relevant theoretical and statistical considerations.
53
54
55

56 **Comparison of models.** As a final step we will compare the resulting models from the
57 substitution-based and exploratory approaches to constructing the MoCA-H and the MoCA-
58
59
60

1
2
3 V. We will compute participant scores on each model by totalling across the correctly
4 answered items, as per the procedure for the standard MoCA. The models will then be
5 compared on a range of key performance indices including AUC, internal consistency
6 (Cronbach's alpha), test-retest reliability (intra-cluster reliability co-efficient), sensitivity and
7 specificity, and optimum cut-point for dementia diagnosis. A choice of the final
8 recommended version of the MoCA-H will then be made on the basis of this comparison
9 along with relevant clinical considerations. Assessment at participants' homes may facilitate
10 performance on the 'orientation to place' questions, reduce stress and impact on the total
11 score. Therefore comparability of scores would be tested with reference to existing MoCA
12 normative data with respect to test site, age and educational level.
13
14

15
16 The result of the above analytical procedures will be finalised versions of the MoCA-H and
17 MoCA-V instruments, in each of three languages (English, French, Greek) together with
18 recommended threshold values for detecting dementia and measures of internal
19 consistency and test-retest reliability.
20
21

22 23 24 **Study start and duration**

25
26 It is anticipated that data collection will start in June 2018 and run for 18 months.
27
28

29 30 31 **Ethics and dissemination**

32
33 This study has been reviewed by local ethics committees in the UK, Cyprus, France and
34 Greece. Ethical approvals were granted by the Greater Manchester West Research Ethics
35 Committee (UK) on 13th September 2017, by the Cyprus National Bioethics Committee on
36 19th January 2017, by the Comité de Protection des Personnes du Sud-Ouest et Outre-Mer
37 IV on 25th May 2018 and by the Local Ethical Committee of Health Sciences and Scientific
38 Committee of the Eginition Hospital of the National and Kapodistrian University of Athens
39 on 15th December 2017.
40
41

42
43 The results of the study will be disseminated through peer reviewed publication, conference
44 presentations, the study website (<https://www.sense-cog.eu/>), the SENSE-Cog Twitter
45 account (@sense_cog) and the MoCA test website (<https://www.mocatest.org/>).

Discussion

The current paper describes the protocol for the development and validation of versions of the MoCA (version 8.1) [11] for the identification of dementia within populations of adults with acquired hearing or vision impairment. Six participant groups will complete the MoCA or a version of the MoCA adapted to accommodate either vision or hearing impairment – the MoCA-H and the MoCA-V. Through a process of item and predictive analyses, we will determine the combinations of items with the best balance of discriminative power relative to gold standard diagnostic criteria, clinical validity and utility, and reliability, within groups of adults with hearing or vision impairment.

The development of the MoCA-H and the MoCA-V draws on the diagnostic strengths of the previously well-validated MoCA. It is anticipated that through item substitution rather than the deletion of items, the MoCA-H for people with hearing impairment and the MoCA-V for people with vision impairment will have superior validity and reliability compared to previously adapted alternative measures [10].

The primary limitations of the present study are twofold. First, due to the complexity of design and the large numbers of participants with specific combinations of cognitive and sensory impairments required, it was not feasible to include a group of participants with mild cognitive impairment (MCI) in addition to normal cognition and dementia groups. The authors are currently seeking additional resources to support addition of an MCI group to the validation sample. Second, the MoCA-H and the MoCA-V that will be developed in the present study rely either on good vision or good hearing. Neither test is suitable for those with dual sensory impairment. Around 1.5% of adults aged over 20 years has a dual sensory impairment (best-corrected better-eye visual acuity >0.30 (6/12, 20/40)) and better ear threshold >25 dB HL across 0.5–4 kHz) [32], so development of suitable cognitive screening tests for those with dual sensory impairment is important. Given the reliance of MoCA items on either hearing or vision function, the MoCA test paradigm is not suitable for adaptation for those with dual sensory impairment. Alternative cognitive screening tests for those with dual sensory impairment are available or in development, based, for example, on touch [33] [34] or smell [35].

1
2
3
4
5 Outputs for the present study will include adaptations of the MoCA suitable for use in
6
7 people with hearing and vision impairments. In addition to this, the study will provide
8
9 validation data on Greek and French versions of the MoCA (version 8.1) in populations
10
11 without sensory impairment.

15

16 **Author contributions:** IL and PD are responsible for the overall development of an ethically
17
18 sound protocol. PD, KG, AP, SS, CT, APC, WKY and ZN developed the MoCA-H and MoCA-V.
19
20 PD, AP and DR designed the validation study and DR planned the analyses. All authors
21
22 contributed to the drafting, critical revision and final approval of the document. Thank you
23
24 to the patient panels who provided advice on the design and conduct of this research.
25
26

27 **Funding statement:** This work was supported by the European Union's Horizon 2020
28
29 research and innovation programme under grant agreement number 668648. PD is
30
31 supported in part by the NIHR Manchester Biomedical Research Centre.
32
33
34

35 **Competing interests statement.** None declared.
